Richard,

Think again about what you wrote. The "Faraday screen" is full of openings between the wires of the picket fence. There is no evidence that anything magnetic or electric penetrates the walls of the conductors beyond a very shallow layer.

Terman certainly did not deny the existence of skin effect that keeps the fields out of the interior of conductors.

Yuri, think about how the "link coupling" magnetic loop you describe
above works. When the loop is energized where does the RF current
leaving the center conductor go? It has to flow onto the outside of the
shield. Where else could it go?

RF current "makes the corner" around to the outside surface of the
shield in coax all the time. If it didn't we wouldn't need choke
balun's.

EZNEC can solve the problem. EZNEC was not available to the
1960 hams. Let's take a 130 foot dipole on 3.6 MHz with
95 feet of 450 ohm ladder-line with a velocity factor of
0.9. 65+95=160 The impedance seen by the tuner is 100-j400.
Virtually every tuner in the world should be able to match
that impedance. The antenna system is resonant around 4 MHz.
The free demo version of EZNEC is available at:
http://www.eznec.com

How does the 1960 ARRL handbook handle velocity factor?

Hi Joe,

It is arguable that the entire roof would even be evenly conducting,
as installed. As conductivity is not a primary concern, the installer
is not motivated to insure that a #8 wire attached to one panel would
be felt by any other with any degree of confidence. Further, even if
all panels exhibited continuity today, this is not to say they would
tomorrow unless some care was taken to insure tight interconnections.

It is not unheard of here in this group to find Hams taking that care
and bonding all panels. The sense of it is to reduce the chance of
developing spurs due to RF currents meeting corroded joints (although,
no one has ever reported this as a problem, only anticipated it).

You really need to type if you run cw over about 60wpm
or so.. That was about my limit as far as sending fairly clean
with a paddle. I never liked to type, so 55-60 wpm pretty much was
the limit for me. Most all the high speed people used a keyboard
to send. But I'd say the majority listened with their ears instead
of using a reader. The brain is a better reader than most puter CW
programs. Most don't handle noise very well. Once I hit 55-60 wpm
on a paddle, I was stretching the limits. Past that, and it was pretty
dang ugly... Slopsville. The keyboards could kick back and type
about any CW speed with perfect sending. A decent typist can go
over 100 wpm+.

Source record: 59070

A270-10S Cushcraft 2m/70cm 5 el Yagi
* Frequency 144-148MHz, 430-450MHz * Elements 5 ea. band * Power 350W *
Forward Gain10dB * Front-to-back 20, 18dBi * SWR (typ) 1.2:1 * Bandwidth
>4MHz, >10MHz * Boom length 1.9m * Longest element 102.4cm * Turning radius
1.8m * Mast Size 32-51mm * Wind load 0.07 * Weight 0.81kg
This antenna can be mounted in either vertical or horizontal polarisation.
It is perfect where space is tight and dual-band operation is required. The
harmonic relationship of 2m and 70cm allows clean radiation patterns with
minimal interaction.

if i can dose it want to be mounted vertical or horizontal polarisation

> How does the 1960 ARRL handbook handle velocity factor?

In Heys book circa 1989, he says "The velocity factor is only of
significance in certain antenna types, for example those requiring
quarter-wave 'stubs'. Such stubs are needed for the four -element
collinear antenna illustrated in Fig 21 and described later. Open wire
lines have a velocity factor of about 0.975 which means that a
quarter-wavelength stub at 7 Mhz will be 10in. (25cm) shorter than a
basic electrical quarter-wave-length."

In my old dusty musty ARRL 1960 and 1983 antenna handbooks I did not
find any reference to velocity factor in using this type of antenna.

Gene,

You might have to find a book that quotes the description of a screen
with parallel wires and large air gaps as compared to a wall or
cylinder several skin depths thick.
:-)

It is most likely the huge dish in Arecibo, Puerto Rico.
Close by would be the HARP system in Alaska.
Then the curtain arrays used by broadcast stations.
Then the Rhombics, then the rest.

I remember my "Elmer" in the 50's adding extra
lengths of open-wire line on certain bands for
his 80m dipole. He said he did it to make his
Harvey Wells Band-Master Deluxe happy. I don't
recall him owning an SWR meter but he did have
a 6C4 homebrew GDO and a sensing loop for locating
current maximum points on the open-wire line. The
transformed impedance is lowest at the current
maximum point.

When I was a Novice, every time I changed bands
from 40m to 80m, I would let my coax-fed dipole
down and jumper across two insulators. That was
the extent of my knowledge half a century ago.

We need RF chokes and baluns to supress curents induced on the shield from
the unbalance at the antenna feedpoint.
Sooo, according to W8JI "teachings", RF current gets induced onto the
outside surface of tubing, then crolls around the edges and goes inside the
tubing?
Sooo, we should cork the elements, or the current will get confused inside
of dark tubing elements, Eh?
Any formulas to calculate the resonance of such "antenna"??

Gene Fuller wrote:
"Terman certainly did not deny the existence of skin effect that keeps fields out of the interior of conductors.'

true. The point is, shielding from magnetic fields is different from electric fields. On page 35 of his 1955 edition, Terman writes:
"Magnetic flux in attempting to pass through a shield (copper or aluminum) induces voltage in the shield which gives rise to eddy currents. These eddy currents oppose the action of the flux, and in large measure prevent its penetration through the shield."

On page 38, Terman writes:
"Electrostatic shielding is obtained by enclosing free space to be shielded by a conducting surface."

On page 45, is problem 2-45 which contains an illustration of a grid of open-circuit wires which "will provide electrostatic shielding without magnetic shielding---." This works just like the picket fences used in broadcast stations to inhibit harmonic transmission.

Terman did not make this stuff up. It was already in wide use at the time.

Best regards, Richard Harrison, KB5WZI

Yuri,

It is true that current will not flow on the inside of a tube from
current on the outside. The "waveguide beyond cutoff" effect keeps it
from doing so. The currents quickly cancel a short distance inside the
tube.

However, if you put a conductor inside that tube (wire) now it acts like a coax cable and the energy on the center conductor couples to the inside wall of the tube. At the end of the tube the current is free to wrap around to the outside.

Amateur Radio Manufacturers and unfair pricing!

Here I sit the day after Dayton, calling around to all the dealers looking for a HF Transceiver. There were some fantastic prices offered on equipment (As much as $500 off list), and the dealers are back to charging full price today.

I am told by the dealers I called, that the Manufacturers were making deals with them so they could sell there inventories much cheaper, and the orders had to be taken at Dayton. Today, the day after when most of these orders had not even shipped yet, they are back up to full retail price.

To be fair, Manufacturers should allow these prices for a time period after Dayton to give other Amateurs who could not drive to Dayton an opportunity to get the same deals.

I think we should all write to them and let them know how we feel. This is unfair !

Cecil,

I read the postings regularly for new ideas on antennas and feedlines.

This recent posting with your ladder-line physical shortening idea is just the solution I was searching for to reduce my ~65' of 300 ohm ladder-line to stand-off my 40' tower and keep it out of my house. Now I can add a coax RF choke loop at the base of my ladder-line feeder (still outside) and feed the rest of the coax into the basement to my shack. I'll likely use knotted black dacron line for the stringer/messenger support.

The antenna is an inverted 204' G5RV - any suggestions on how many RG-8X turns and what diameter choke loop to use for mostly 160, 80 and 40 metre band operations with this antenna - I was thinking about 8-9 turns on a 9" loop? I plan to have it about 37' up with the ends dropping down to 20'. I know it will be mostly a cloud-burner at this height, but it is the best I can do given my tower height and tree availability and it will get me on 160M.

Thanks....... Al, va3kai

Cry us a river. They made the offers at Dayton and that was what they as
private businesses chose to do. You could have either went to Dayton or
found whatever way to get a radio from there. Get over it.

>
> We need RF chokes and baluns to supress curents induced on the shield from
> the unbalance at the antenna feedpoint.

Actually what oftentimes happens with a coax feed is that the RF
current leaving the inside of the feedline shield can flow in two
directions. It can flow down the antenna element half connected to the
shield (desired path), or it can flow down the outside of the shield
(undesired path). The electrons are dumb, all they are looking for is
the path of least resistance. They can't tell that the metal surface
on the outside of the coax isn't supposed to be part of the antenna.
The only way to keep current from flowing down the shield is make
the antenna element-half connected to the shield look like a lower
impedance than the outside of the shield. If you place ferrite beads
around the outside of the shield, this will raise the impedance of the
shield path, thereby diverting the bulk of the RF current into the
element-half and off of the shield's outside surface.

> Sooo, according to W8JI "teachings", RF current gets induced onto the
> outside surface of tubing, then crolls around the edges and goes inside
> the tubing?

As per K4FMX's comments, this can only happen if there is a
center conductor inside the tubing, or if the tubing diameter is greater
than ~1/2 wavelength in diameter, otherwise the inside of the tubing
looks like a circular waveguide beyond cutoff. This is why coax
of a given diameter becomes useless above a certain upper frequency
limit. Once the I.D. of the coax becomes a significant fraction of a
wavelength in diameter, the coax will start to support propagation of
waveguide modes (e.g. non-TEM modes). At HF frequencies, even
large diameter tubing is well beyond waveguide cutoff, so there is no
concern about "corking" open tubing with no center conductor (it
corks itself).

2899. Re: can i use this for satalite working A270-10S Cushcraft 2m/70cm 5 el Yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-22 16:51:13 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <e4sq62$371$1@news.netins.net>
Source record: 59091

With a couple of caveats, yes, you can use it for satellite work.

1. Rear mount it, don't shoot through a metal mast.

2. Polarization: for LEOs won't matter (Low Earth Orbit). Since there aren't any HEOs right now, do whatever might give you dual use, e.g., if you want to work the occasional SSB contact then mount them for horizontal polarization. If, on the other hand, you want some increased FM repeater coverage, mount them for vertical polarization. As far as the LEOs go, polarization won't be a real factor.

3. Chances are neither antenna comes even close to claimed gain. It won't matter for the LEO, they are good enough.

Some of the best fun you can currently have on satellites would be dramatically improved with a 2m preamp. Do yourself a favor and mount it out at the antenna, not after 2 or 3 dB of feedline loss in front of it. The mode B VUSAT works really well. Lots of fun to be had on it. ISS also works well (International Space Station). Old AO-7 still works (after being on an extended vacation for a decade or so) nicely on mode B, WHEN IT IS IN SUNLIGHT (batteries are shot)).

Any bird that you work that has a 70cm downlink (your received side) will require a preamp unless you have no feedline loss at all.

In summary, the antenna will work. Make sure to keep your feedline losses as low as possible. Nothing less than LMR-400 will do if you have any significant length of run to the antennas from the shack. (25' or more). Preamps at the antenna will make a night and day difference. They are the SINGLE thing you can do that will give the biggest bang for the buck. I recommend the SSB Electronics preamps as they are rugged, well built and well protected.

Have fun.

My sat setup:

2m/70cm nested quads (5el-2m/8 el-70cm), vertical polarization, mast mounted gasfet preamps
70cm 14.2 dBc circlularly polarized (RHC) crossed yagi M2
2m Egg Beater
3' parabolic dish for 2.4 gig, antenna mounted LNA down-converter.
All antennas fed with 80' of LMR-400.
AZ/EL rotors: G-800 AZ, Yaesu Elevation Rotor.

IMO, turns of coax, like 1/2WL of feedline, doesn't make much
sense on 160m because of the number of turns required. Turns
of coax on a large toroid makes more sense at the low frequencies.

Just for the heck of it , I did a little internet check on Arecibo and found
the following info;
""Full operation of the facility ideally requires three frequency bands,
near 3.175, 5.1, and 8.175 mhz."

IT IS!
It has been used by hams as low as 3.5 MHz band.

Seems like Arecibo might have around 36dB gain at 28MHz where it is a
28 wavelength dish, at least according to scaling numbers I found on a
random webpage.

Not bad. Seems that a 3.5 wavelength dish (3.5MHz Arecibo) still has a
bit of gain too. 15dB?

I wish I had 15dBd gain on 3.5MHz... don't exactly want it straight up,
though.

That's OK. Just hoist up one mountain, lower the other, and rotate
the whole dish/valley onto its side. Paul Bunyan would have thought
nothing of it.

I am just about to install a hamware AT-502 in my back garden to tune
a 67ft doublet fed with ladder line. On 1.8MHz (and sometimes on 3.5 &
7MHz) I'll be using the ASU-502 accessory switch, strapping the
feeders together and tuning it as a T against a crappy ground .
I'll let youse all know how it works out.

From: ml <m@di.net>
Message-ID: <m-CF4A28.19192122052006@news.verizon.net>
Source record: 59107

hi

I was wondering a few things i read about in my sgc tuner manual about dipoles

a) they say or sorta recomend that if your making a simple horiz ctr fed dipole, it's 'best' to have one leg longer

why is that 'a good idea' what happens that makes this sorta advisable

b) they recomend the longer leg to be the rf 'ground'' side , really confused as to why, my gut would tell me to make the hot side the longest leg so i am confused

can anyone help me understand the above, i kinda understand how the wave looks on a regular horizontal ctr fed dipole is

any help appreciated

2916. Is the little ball on top of my antenna the ionsphere?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-22 23:28:15 UTC
From: Jay <Jpegged@b4qrt.net>
Message-ID: <jOrcg.651$Sf2.175@newsread1.news.pas.earthlink.net>
Source record: 59108
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.policy,rec.radio.shortwave

I put the ball to a metal grinder and I could easily see an outer F layer and then the E layer. I couldn't find a D layer, but it was dark outside and there's not supposed to be a D layer at night. Neat how antenna's can be manufactured to do that.

Just passed my tech and General on Sunday so I'll be on the bands as soon as I find out my callsign and get an ionsphere for my antenna. I destroyed the old one on the grinder and I hear you need a good ionsphere to shoot good skip and hear far away stations. Reception has been really shitty lately without the ionsphere. I looked through the last 4 issues of QST and I couldn't find anyone selling ionsphere's. Where can I get one, or do I have to buy a whole new antenna?

Thanks, Jay

You don't need a new one. The old one probably got stuck in your coax
by back-feed when you were grinding. Just get an RF brush and give your
coax a few swipes and the ionosphere should pop right back out!

Hi Buck,

I built one some 10 years ago for what I call my Binary Variable
Transmission Line. I had obtained some precision transmission line,
that is solid copper shield (no vinyl jacket), but RG-58 size and I
coiled it in 6 inch loops of 1', 2', 4', 8' and 16'. I then used 5
DPDT switches to add the sections in, or to jump them. I mounted it
in a box and it works fine.

You cannot use 50 ohm coax to transform the impedance to
50 ohms since 50 ohms is the center of the SWR circle.

You could use side-by-side runs of 75 ohm coax to achieve
a balanced Z0 of 150 ohms.

But the reason that 450 ohm ladder-line works so well is
that 450/50 = 9:1 and 4050/450 = 9:1. 450 ohm ladder-line
can handle most any and all of the antenna impedances with
an SWR less than 18:1 on the ladder-line.

Forgot to say the above applies to dipoles that are 1/2
wavelength on the lowest frequency of operation. It
doesn't apply to dipoles that are much shorter than 1/2
wavelength.

Since Cecil's scheme operates the transmission line at very high VSWR
on some frequencies (no matter what the line Zo), lossy lines such as
typical coax may (probably will) have unacceptable losses on some
frequencies.

But of course you realize that the function y = mx + b doesn't meet the requirements of a linear function when applied to network theory.

Either Cecil is misquoting me, or Richard is misquoting Cecil.

Cecil calls the total current the "standing wave current". I never said that the standing wave current isn't sinusoidally shaped. I said that the *envelope* of the standing wave -- that is, a graph of the magnitude of the current on a transmission line as a function of position along the line -- is not sinusoidally shaped except in the special case of a complete reflection. This isn't a personal theory, but a very well established fact which can easily be derived from fundamental equations. (Or it can even be found clearly stated in texts for those unable to understand the derivation.) On antennas, the current distribution (magnitude of current vs position) is generally not sinusoidal either, although it's approximately so on thin wire antennas.

Assuming that the transmission line is driven with a pure sine wave, the forward, reverse, and total currents as a function of *time* will be sinusoidal and consequently no harmonics will be generated. (I'm of course neglecting nonlinear effects which might occur in a real transmission line or antenna such as magnetic conductors or nonlinear dielectrics. But in practical terms these will be virtually unmeasurable with ordinary coax or twinlead and amateur power levels.)

It's hard to determine whether Cecil's sustained confusion between a time waveform and a graph of amplitude vs distance is intentional or if the concepts are really mixed up for him. It has, in either case, provided a convenient diversion from his basic strange theories at the time it was getting particularly hard for him to continue supporting them.

It is the same reason that when you build a standard 2 meter ground plane antenna, that the ground plane is constructed with wires or rods about 20.5 inches each. That is close to a quarter wave without compensating for end effect. The radiating element is about 19.5 inches which does take the end effect into account.

It will result in less RF on the outside of the coax.

2935. Question about the uses for an antenna design

Source record: 58977

I have determined a way to feed four dipoles to provide good horizon to horizon coverage at all angles for circularly polarized signals. It works quite well for Low Earth Orbiting satellites. I lack the skills needed to analyze the concept. I would like to make this concept available to anyone who wants to build their own antenna.
I have a working model that seems to have no serious minimums when receiving NOAA satellites at 137 MHz. The concept is quite simple and probably easily understood by any antenna engineer.
Does anyone know where I might locate someone who would have interest in knowing about this antenna concept that I have chosen to call the Cross concept.

Hi All,

I acquired a Pitch-Prop motor a number of years ago, with the intention of building a antenna rotator.
I still have the intention of doing this, and have checked the motor for operation. This works out very nice, and was able to control it to different speeds with different voltage.
I have a construction design for the mounting of the motor and gearbox to the tower, and antenna.

The problem I have now, is I wish to construct a suitable control unit, with digital readout, and the possibility of controlling via a mini PIC control, or via PC.

I have searched the internet without much success, so my next course of action was to see if anyone on these groups might be of help.
So I put my hands up for HELP! :)

Any help would be gratefully received.

Thanks in Advance.

Kevin, ZL1KFM.

I knew what Richard meant. Quoting "Linear Network Theory",
by Ferris: "In the functional relationship, h(t)=kf(t), no
matter what h(t) and f(t) represent, the relation h(t)=kf(t)
must be linear. ... An elementary concept, then, is that h(t)
and f(t) are related by a straight line of the form
h(t) = mt + b."

> Either Cecil is misquoting me, or Richard is misquoting Cecil.

Richard quoted me correctly. I did *NOT* quote you. I merely
stated what I thought you said.

> Cecil calls the total current the "standing wave current".

That is absolutely false. Total current equals standing wave
current plus traveling wave current. Or standing wave current
equals total current minus traveling wave current. Subtract
out the traveling wave component and a pure standing wave
component is left.

Note that you did not quote me. You merely stated what you
thought I said and you were mistaken.

> I never said
> that the standing wave current isn't sinusoidally shaped. I said that
> the *envelope* of the standing wave -- that is, a graph of the magnitude

> the line -- is not sinusoidally shaped except in the special case of a
> complete reflection.

The envelope of the standing wave current is the same whether
reflection is complete or not since the traveling wave current
has been subtracted from the total current.

Seems you should have said the total current envelope is not
sinusoidal. The standing wave current envelope is obviously
sinusoidal since the traveling wave has been subtracted.

> This isn't a personal theory, but a very well
> established fact which can easily be derived from fundamental equations.

Please provide a reference that says after the traveling wave
current has been subtracted from the total current, the resulting
standing wave current envelope is not sinusoidal.

> (Or it can even be found clearly stated in texts for those unable to
> understand the derivation.) On antennas, the current distribution
> (magnitude of current vs position) is generally not sinusoidal either,
> although it's approximately so on thin wire antennas.

Just because the scale of the position axis changes with VF doesn't
mean things become non-sinusoidal.

> Assuming that the transmission line is driven with a pure sine wave, the
> forward, reverse, and total currents as a function of *time* will be
> sinusoidal and consequently no harmonics will be generated.

This statement contradicts what I thought you said before. Seems
we are now in agreement.

> looks on a regular horizontal ctr fed dipole is

That suggestion does not make very much sense.

First, a ground isn't a "better ground" just because it is longer. The lowest impedance and "best" ground or counterpoise occurs when the ground is exactly resonant.

Second, the least common mode current is influenced heavily by the length of the feeder, and is often the least when a dipole antenna is evenly balanced.

The only possible reason for that is to moderate the impedance presented by the antenna, but again that would also take special consideration of the feedline length.

Even a 1/4 wl groundplane does not improve from radials longer than 1/4 wl. As a matter of fact it often gets worse.

Maybe you should ask them why they want customers to do that. It sounds like witchcraft to me.

Roy Lewallen, W7EL wrote:
"But of course you realize that the function y = mx + b doesn`t meet the requirements of a linear function when applied to network theory."

Works for me.

Linear means the graph of the function is a straight line.

f(x) = y = mx + b is called linear because its graph is a straight line.

A straight line is the shortest distance between two points.

In y = mx + b, m is a constant determining the slope of the line. x is is the independent variable. b is the offset or point along the x-axis where the line crosses.

y then is a linear function of x because its slope is always mx, but displaced in the x-direction by a constant value, namely b.

y is linear the same as IR is linear, or by substitution, E is linear in Ohm`s law where E=IR. For any value of I, voltage = IR and the graph of I versus E is a straight line with a slope equal to R.

Resistance is a common factor in network theory.

Best regards, Richard Harrison, KB5WZI

Excepting the readout, this should be a fairly routine motor control problem. Depending on what you want to do your control box could be as simple as a current-limited power supply and a couple of switches or as complex as a fully fed-back motion control system.

How's your electronics skills, and how fancy do you want it to be?

The ARRL Product Catalog at the link
http://www.arrl.org/catalog/?item=7571#top
lists a book titled "Stealth Amateur Radio", with a second printing in 2001. However, the catalog entry for this book has "SOLD OUT!" in bold red font. A check for this book on eBay finds one copy available for $100!! I then called the ARRL store and was told that they didn't know when this book would be reprinted and made available. The clerk mentioned something about needing to get the author's permission first.

Since there appears to be a demand for this book, why wouldn't the ARRL rush to get this book reprinted and posted for sale? BTW, is this book any good?

Roy Lewallen, W7EL wrote:
"Either Cecil is misquoting me, or Richard is misquoting Cecil."

I apologize if I misquoted anyone. It was unintentional,

On page 239 of Kraus` 1950 edition of "Antennas" he wrote:
"It is generally assumed that the current distribution of an infinitesimally thin antenna (l/a=infinity) is sinusoidal, and that the phase is constant over a 1/2-wavelength interval, changing abruptly by 180-degrees between intervals."

Cosine has the same shape as sine. They are identical except for a 90-degree phase displacement. Sine starts at zero. Cosine starts at one.

Sinusoidal covers both sine and cosine shapes.

What did you have in mind? Do you want to profit from the idea, or just make it freely available? Just what help (if any) are you looking for: help with analysis, help with writing a description, help with promoting it, help reviewing the idea and comparing and contrasting it to previous ideas, or what? There are lots of folk here who could potentially have an interest, and some even have a deep enough understanding of antennas that they might actually be able to help.

Cheers,
Tom

Is it something like the Lindenblad?

http://www.phys.unsw.edu.au/~map/weather/notes/buildyourown/lindenblad.html

I'm always interested in an antenna design. Making some drawings or taking some photos (or both) and putting them up on a website with some measurements is a fine way to publish your construction.

If you are trying to make some money, I can help for some percentage to be decided :-)

Seriously, though, everyone would be interested in the concept. Put it up on a webpage, even if just a couple of photos. I think QSL.net and some other sites will give you hosting.

I thought I was following this somewhat, but now it appears that I am not.

I thought there were two traveling waves, forward and reverse, with the reverse wave being a reflection of the forward wave from the end of the antenna. I thought that the total current was the sum of the two waves, could be measured with an ammeter, and that it could be referred to as the standing wave.

Are you now saying that the standing wave and the reverse wave are the same wave?

Confusedly,
John

Yikes! Give me $100 and I'll keep putting up steath amateur radio ideas on www.n3ox.net... oh, but I guess I'm going to keep doing that for free.

I doubt the book is quite that good... I'd like to read it since I'm stuck in an apartment for a while.

I imagine that it's like the other ARRL station/antenna books, there are a lot of things that you would have seen other places, as there are plenty of flagpole and magnetic loop antennas, but there are still some novel approaches and good reference material for things you need to look at again.

It is a bit strange that they're awaiting permission from the author... maybe he's incommunicado or something.

I'm going to recommend against electronic feedback unless you are a control systems hobbyist... I did PID (proportional-integral-derivative) servo on a homebrew rotating mast so I didn't need a readout and eventually decided to go with a rotation sensing pot, a voltage-to-current converter, and a surplus meter.

This was after I tweaked the PID to get rid of the oscillations but still had some average position errors...

I guess with a digital system it would be easier to optimize. Mine was all analog... and only one op amp, so the settings interacted :-)

Making the motor go and watching the meter is a more sensitive and intelligent form of feedback, as long as you've got a system you can't break by turning too far.

A simple pulse-width-modulator for speed control might be in the cards though. That way you send a variable duty cycle full-on full-off pulse train to the motor. Good torque and you don't need a variable power supply just to run the rotor.

I'm going to add one to my rotator soon... I've got that on manual right now... pulsing the switch makes a nice slow smooth rotation!

If you do like electronics projects for the sake of electronics projects, feedback control is an interesting way to go, though.

> the standing wave.

If the antenna were lossless, that would be true. However, the
antenna loses RF energy to radiation, ground, I^2*R, etc. Since
the same thing is true of a transmission line, let's first look
at a transmission line.

Let's say we measure (at the tuner)
a forward power of 100 watts and a reflected
power of 80 watts. We can assume that the losses in the line
and the power delivered to the load add up to 20 watts. The
20 watts can be associated with a pure forward traveling wave.
The other 80 watts of the forward power and the 80 watts of
reflected power can be associated with a pure standing wave.
The equations for such would look something like this.

Itot = Ifor*cos(kx+wt) + Iref*cos(kx-wt) =

Itot = I1*cos(kx+wt) + I2*cos(kx)*cos(wt)

I1 would be considered to be the part of the traveling wave that
is delivering net power to the load. I2 would be considered to be
the standing wave current delivering no net power to the load.
It's just another way of mathematically partitioning the currents.

Let's assume for the sake of discussion that the forward wave at
the antenna feedpoint is 100 watts and the reflected wave at the
antenna feedpoint is 80 watts. That means there are 20 watts of
total losses. We can partition the currents in the same way that
we did in the transmission line.

Incidentally, if we assume the antenna is 1/2 wavelength with a
Z0 of 600 ohms, we can calculate the feedpoint impedance just as
if it were a piece of transmission line with a resistive termination.
Anybody want to try that exercise? What impedance is seen looking
into a 600 ohm 1/4WL open stub when the forward power is 100 watts
and the reflected power is 80 watts?

> Are you now saying that the standing wave and the reverse wave are the
> same wave?

The reverse wave is half of the standing wave. The other half of
the standing wave is part of the forward wave. One might say that
the energy in the reverse wave neutralizes the ability of the
forward wave to deliver that same amount of energy to the load.
And indeed, we know the power delivered to the load is the forward
power minus the reflected power.

Will wrote:
"Does sea water make a good enough ground without radials?"

It`s the best you can get in a boat at sea, The point is to get a good connection to the sea. You don`t need radials for that. That`s why a thin copper plate is recommended. Copper is durable and poisonous to sea organisns which may foul the surfaces of other materials.

Skin effect applies. Bolting to a spot inside a metal hull means the RF must travel from the bolt location inside the hull (it can`t penetrate the hull) to an edge where it reaches from the inside surface to the outside surface and thence to the waterline.

DC resistsance of a conductor is resistivity x length divided by crossection. AC resistance is more but proportioned to the DC resistance. A large crossection or area produces a low resistance. That`s why the plate is better for contacting the water than a wire. Its also why the seawater has a low resistance despite a higher resistivity than copper. The huge crossection of seawater has very low resistance in most cases and its reactance is low too. Low resistance and low reactance make a good path for RF.

Tom,

I expect there's not supposed to be any feedline between the antenna
and the tuner in this installation, so I think that it probably is to
moderate the impedance for a ham band antenna cut for the lowest band.

It is witchcraft, but if you're selling antenna tuners to people who
don't know anything about the impedance issues with an all band wire,
it's better to give them a rule of thumb to avoid cooking the tuner,
especially when they don't read the bit in the manual where it's a
"100W" tuner on SSB and they fire up on RTTY.

BKR, where did you get that explanation?

I think you should measure the RF on the outside of your coax when it's
an odd multiple of a quarter wave long including the loading effect of
the case of the radio and the ground half of your dipole is made 5%
longer than the other half.

Listen to Tom. He knows common-mode current on the feedline!

It's actually working pretty good right now and I have the ladder line
all symmetrical in the way it's routed from the antenna. I'm using my
original 126 ft long horizontal wire fed in the middle with 450 ohm
ladder which is 67 feet long going to my Johnson KW matchbox. It tunes
it on 75 and 40. 40 is a little tricky but I can get there ok. I also
use this same antenna as an inverted L on 160 by re-routing the ladder
via a knife switch to my Drake MN-2700 tuner. It tunes very nice on
160. When I get time from painting the house and other chores I will
try to sit down and learn EZnec, then tweak the feedline and maybe the
antenna too. I wish I had more room, I love to experiment with wire
type antennas.

Hi Dan,

If anything, going digital has all the prospects of thrashing the
antenna into shreds. The oscillations you speak of are eminently
suited for an analog solution - you simply have to understand the
nature of resonance, coupling (over, critical, and under), and attack.
If you don't, translating them into binary code will be impossible.

For instance, your average position errors were probably due to
under/overshoot and a too heavily dampened system with too much gain.
No computer program is going to improve that.

Richard,
Agreed on the suitability of an analog solution... I certainly made some steps toward critically damped operation. My circuit design was bad, though.

I didn't have a very analyzable problem; the rotator rotates one of those fiberglass surplus military masts with respect to another, so I get a lot of stick-slip, especially if there's a breeze (there are 12 feet of mast above this thing).

This is not to say a suitable set of P, I and D couldn't be found, and it would have been pretty slick if I'd set up right for empirical loop tuning, but I hadn't done that. I got pretty close by soldering components in and out.

I would have had a better time with a real multiple op amp circuit with a knob for each of P, I and D.

I think you hit the nail on the head regarding too heavily dampened with too much gain in the antenna rotator case. I just couldn't really tune the thing.

In my case, I just decided to throw up my hands and go to the simplest method so I could get on the air with a rotating antenna. I have a quite successful analog servo going every day with my remote antenna tuner (www.n3ox.net/projects/servo). That one is ever-so-slightly underdamped, proportional only, and works nicely. There's a little bit of hysteresis and it certainly could be improved, but I stopped at the good-enough-for-daily-operation level.

I guess what I meant by "going digital" was that depending on whether you're more comfortable with programming than a soldering iron (not me!) you might think about having a simple motor drive circuit and implement the admittedly complex PID loop in software/firmware.

You're absolutely right that you can't do this if you don't know how to do the analog...

73,
Dan

I could have sworn Cecil had used it in that sense before. But Ok, I'll go along with the new definition. Any basic analysis of transmission line operation shows that the total current is simply the sum of the traveling wave currents. Consequently the "standing wave current" as defined by Cecil is zero. So by "standing wave current", Cecil means zero.

This is getting stranger by the day.

I'm sure that somewhere in one of your texts you can find the definition of linear as applied to networks. Once you do, though, a little thought is required to discover that y = mx + b doesn't satisfy the criteria for network linearity.

To be linear, a network has to satisfy superposition. This means that:

If y1 is the response to excitation x1 and y2 is the response to excitation x2, then the response to x1 + x2 must be y1 + y2.

Let's try that with your function.

The response to x1 is:

y(x1) = mx1 + b

The response to x2 is:

y(x2) = mx2 + b

The sum of y(x1) and y(x2) is:

y(x1) + y(x2) = m(x1 + x2) + 2b

But response to x1 + x2 is:

y(x1 + x2) = m(x1 + x2) + b

These are not equal as they must be to satisfy superposition and therefore the requirements for linearity.

Seems pretty clear to me, Roy. The effectiveness of a copper strap around a mains-frequency power transformer at reducing the exterior magnetic field is well known and often used. It's all very clear from Faraday's law of magnetic induction: the net magnetic flux through an area enclosed by a perfect conductor may not change, so time-varying magnetic fields are perfectly blocked by perfect conductors. Copper's a reasonable approximation of a perfect conductor in the case of RF shields.

Cheers,
Tom

It would only be a clear statement to those who understand what was
quoted from Terman.

If a person is confused by or somehow DOESN'T understand what Terman is
saying, he or she might take it to mean magnetic fields can travel
unimpeded through a shield.

It sure is difficult to drive a stake through the heart of myths like
the loop shield "shielding the electric field and not the magnetic
field" when clearly written text in dozens of engineering textbooks is
misunderstood.

Hi Tom,

However, Richard's explanation is the analogue of the effectiveness of
a copper strap (with a non-contacting overlap so as to not be a
shorted turn) between windings of a mains-frequency power transformer,
and grounded to provide electrostatic separation of the two circuits.

No, Not an Ionsphere Post, just a guy who has no clue about the
technology that he wants to use, and he is asking questions, trying
to learn. From the replys he has received so far, he is finding out
that 99% of the hams, don't have a clue about MF/HF Marine Radio
Antenna systems Design, either. I suggest that he head on over to
rec.boat.electronics, and ask Larry, Gary S., Old Chief Lynn, or one
of the other Old Salts, that have been doing these installations for

decades, and have the experience in the technology being asked about. Most hams think that MF/HF Marine Radio Antenna Systems design should follow the same rules that Land Startions use. Well that isn't the case, and usually ends up is a "Piss Poor", marginal system that only talks "when the Band is open", and "when the Band is open" even a wet noodle will radiate enough to communicate.

A few additional questions along these lines for the group (with some paraphrasing):

1. What is the skin depth in salt water at 14 MHz? How would this affect a ground plate at four feet below the surface?

2. What would the ohmic losses be over a one square foot by 33 foot path through salt water?

3. How well would the ground plate work on fresh water bodies, such as much of the Chesapeake, the Great Lakes, and various rivers and tributaries often used by cruisers? How would it compare with radials over fresh water?

4. Can anyone cite a published and reproducible study in which the RF losses through salt water were measured and compared with losses through

one or more copper wire "radials" on or below deck of a typical cruising vessel? Or is there a published theoretical analysis of this comparison? Looking for more than the casual, anecdotal stuff.

5. Will a four foot length of wire dropped into saltwater provide a "good" RF "ground" and on what is the answer based?

I need enlightenment!

Thanks, and 73,

Chuck

Your last two statements are false. Please stop trying
to tell others what I mean when it is obvious that you
don't know what I mean.

> This is getting stranger by the day.

Why can't you and I just have a reasonable technical
discussion? Sooner or later, the readers who care at
all about the truth are going to see through your
attempts to falsify what I have said.

Since you obviously have not understood what I said in
the past I guess I need to simplify it for you so here goes:

Let A be the forward traveling current.

Let B be the rearward traveling current.

Let C be the part of the forward traveling current
that flows through the load.

Let D be the part of the forward traveling current
that doesn't flow through the load and becomes B
after being reflected.

A = C + D The total forward current is divided
into two components, one accepted by the load and
one rejected by the load.

The following is phasor addition

Total Current = A + B = (C + D) + B = C + (D + B)

(D + B) is the pure standing wave current component,
a part of the forward current equal to the reflected
current.

The total current is indeed the phasor sum of the
forward and reflected current.

The total current is also the sum of the load current
plus the pure standing wave current. The pure standing
wave current envelope is sinusoidal.

Well, I'd probably call it "lore", as in "Everybody says that it seems
to work better that way."

I don't think it has anything to do with the actual RF radiation
behavior of the dipole antenna, once a match is achieved... it
shouldn't matter for this purpose which side of the dipole is longer.
I think it has everything to do with the tuner's ability to find a
match.

As I understand it (and this is all second- and third-hand knowledge):
the SGC tuners (like the SEA tuners from which they're said to have
been copied and like a lot of similar tuners from Motorola and others)
were designed primarily to match short verticals (whips and wires)
working against a much larger ground system. They're designed for
unbalanced applicatios. Their original application was marine and
vehicle use, with the tuner very robustly "bonded" to the metal
chassis of the vehicle. The manuals still make it clear that a large,
well-bonded ground/counterpoise system connected directly to the tuner
chassis is what these tuners really "want to see". The acceptable-SWR
range for a dipole to be matched is rather limited... IIRC the SGC-230
manual says that it's limited to 5:1 or so.

When used to center-feed a dipole, making the ground-side leg longer
than the hot-side leg increases the capacitance to ground on that side
and may tend to mimic the environment for which the tuners were really
designed.

As to _why_ they want to see it - my guess is that it has to do with
the details of the tuner's internal circuitry (it's an L or PI tuner),
the tuning-setting search algorithm in the microprocessor, and perhaps
the electrical details of the SWR-and-impedance measuring/bridge
circuit.

The manual comments that if the counterpoise system isn't
significantly bigger than the radiator, the tuner's microcontroller
may "become confused" and try to feed power to the ground system
rather than to the radiator. Yes, I know, this doesn't really makes
sense electrically... I suspect that it really means that the
matching-component search algorithm starts making decisions which
actually drive the system further away from a good match rather than

towards it. It's also possible that such installations are more prone to high levels of RF current flow on the feedline from the transmitter, and also to high common-mode RF flow on the power and control lines, and that this RF might tend to confuse the tuner's SWR-and-impedance sensors and thus disrupt the match-search process.

My own experiences with an SGC tuner seem to confirm the limitations and warnings that SGC publishes about the hookup required to establish a match. A couple of years ago I picked up a first-generation SGC 230 (apparently never used, as it was still in the original shipping box and bag) at a hamfest for all of $30. I've tried it, and I _can_ get it to work, but in my installation it's finicky in the extreme about its ability to match a wire.

I've never had any success in getting it to match a dipole. It doesn't do well at all when trying to match a longwire (even one of what the manual says is an optimal length) when mounted on my house wall... I suspect that the 8' of wire between the tuner case, and the point at which I've bonded my counterpoise/radial/ground system, has too much inductance.

It also seems to be sensitive to which radio it's used with. It "likes" my old Ten-Tec Scout better than my new Kenwood TS-2000 - it'll achieve a match for the former that it won't achieve for the latter. I suspect that the problem is that the TS-2000's transmitter has SWR-sensitive power foldback - the TS-2000 keeps changing its transmit power as the SGC switches between different match-component settings, and I believe that this is completely confusing the SGC's search logic. Using the same tuner and antenna, on the same frequency, with the Ten-Tec (which doesn't use an SWR-sensing power reduction circuit), a match can often be achieved in a few seconds.

I've given up trying to use it for my home station, as I haven't been able to put together a reliable installation with it. I'll keep it around for field use - grounded to a vehicle or a big chain-link fence or something like that, it may work well enough.

My conclusion is that these L/Pi long-wire tuners are really best suited for the uses for which they were designed... matching a whip or wire, fed against a Big Yellow Taxi or some other large mass of sheetmetal or a really good radial system. For feeding a balanced antenna, I think you may have better results with a tuner which is explicitly designed for that sort of job.

Possibly SGC has improved the matching/searching behavior of their tuners/couplers when used in balanced-antenna applications, in the newer versions. The one I have is at least ten years old, I think - so old that it's in a non-weatherproof aluminum chassis rather than a weatherproof plastic one, and it doesn't have the "tune lock" feature of the newer ones. Dunno for sure.

You have missed the point, Roy. It is the relationship between
functions that has to be linear. If f(x) is the input and y
is the output where y = h(x) = k*f(x), a plot of the output
Vs input will yield a straight line of the form mx + b.

I have asked this simple question a number of times and, so
far, no one has answered. It should have a simple answer so
here it is again. Does a 60 Hz magnetic field travel virtually
unimpeded through a coax shield? This question involves 60 Hz
noise being coupled through coax.

2993. Built Mobile using Lewallen "fat dipole" concept

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-23 20:33:16 UTC
From: gene@csl.uiuc.edu
Message-ID: <e4vricjfp1@news.ks.uiuc.edu>
Source record: 58935

I built a Hi-performance 75 meter Mobile antenna based on Roy Lewallen's explanation of how a car body should ideally be used as the "fat" lower portion of a vertical dipole. Ideally, the mast should be placed at the top center of the car for good symmetry, but this is usually impractical for 75 meters in motion with a 13 ft height limit.
But on my 96 Dodge Ram truck, this idea was more practical. The truck box (mine was short bed) is separated from the cab in the upper area above the frame. To utilize the truck box as a "fat" vertical lower portion of a vertical dipole, I mounted an aluminum rail between the top edge of the box sides, so that the center of the alumimum rail becomes the highest electrical center of the box. The mast is mounted here (insulated) and becomes the feed point for the coax. But to prevent the "grounded" feed coax from compromising the "elevated" feed point, I coiled several turns of the feed coax (RG-58) thru a few large ferrite cores from my junk box. Presumeably, this minimizes any horizontal currents on the coax shield and thus minimizes ground losses. As Roy points out, horizontal currents near ground are readily coupled to ground and become losses.
The "theory" is that the horizontal currents leaving the top-center feed point are symmetrically equal and opposite (as in radial systems) and neutralize for minumum horizontal coupling-to-ground.
Conversely, all the vertical components going downward in any and all parts of the truck box are additive, in addition to the fact that vertical currents are much less coupled to ground, and less ground loss.
My apology if I am misrepresenting What I interpreted from Roy's comments. If so, perhaps he, or someone else will correct me.
Note that with this system, there is no reason, or need for any additional bonding, or ground straps, (unless you assume that the hinge and latches on the tail-gate are insufficient). I had an aluminum tool box mounted at the rear of the box, but it did not touch the sides, so assume it had little effect. (Now that I think about it, I probably should have strapped its top edge to the top of the truck box, for an extra current path).
My mast is concentric 1" each nearly 6' length. With loading coil and unique top hat, the mast is adustable for 13' legal limit traveling, or extended to 19' top height for extra performance while parked, or camping.
Hoping to capture some attention from the High-power, Big-antenna discussion groups, I first went all out with the 19' high camping version with an especially Hi-Q loading coil, and extended with 75' of RG-58 (small coax) into the ham shack so that I could use a 1Kw linear.
For the Hi-Q coil, I twisted two strands of #16 bare solid tinned copper wire (using an electric drill), and wound about 40 turns on a 4.5" diameter form with wax paper around it. I put a strip of clear RTV across the turns in two places. At a third place, I notched a piece of 3/4" PVC and supported each turn with RTV, with additional nylon strap at the first and last end turns, so it was essentially and air-wound dielectric between turns. The coil

length was about 9" for a 2:1 L/W ratio. I believe the inductance was about 80 microhenries.
The mast portion to the bottom of the coil (camping version) was about 10'-10" and the coil terminals were about 10" apart.
The "unique" capacitive-hat was cylinder-like, and resembles an upside down waste basket of 1/2" square grids of galvanized wire (i.e. 1/2" hardware cloth). #14 copper clad steel wire is tack soldered in several places to provide more rigidity, as well as minimizing corona losses. Dimensions are about 1' diameter and 14" deep. It is attached to the top of the coil by four struts about 12" long (#14 copper-clad steel) angling to the center at the top of the coil. Physically, the coil/tophat assembly is supported by a section of 3/4" PVC which goes from the top of the capacitive-hat (actually the bottom of the "upside-down waste basket), down to overlap the 1" mast, and is "grooved" and clamped with hose-clamps.
For adjusting the concentric masts, the lower one is cut about half way thru about 1/2" down an with a slit opening to allow a hose clamp to compress it to the upper mast for adjusting height.
Admittedly, the 13' road version is a little ugly for road travel unless you're strongly motivated. I used black nylon guy ropes (found at Menards and are about the size of flat shoe laces) which are not so noticeable and conveniently attach to the four "post holes" in the truck bed. The low wind resistance of the 1/2" mesh is low enough for high speed driving. But the Camping version should be quite acceptable for parked, or camping.

The final conclusion among a 75 meter discussion group who have years of almost nightly activity among members who use high power and and nearly optimum antenna systems, was that the performance was surprisingly similar to that of several of the members of the group, and exceeding some.
I only used it one nite with the 13' drive version before I moved the truck, but it also got surprisingly good results. Of course I realize that hams become jaded by the many claims they hear about antenna performance so they will factor that into this description also.

I forgot to mention that the "capacitive-match" method that I used across the feed-point required about 1200 picofarad. This is good news because we know that the actual radiation resistance is quite low (perhaps 2 to 5 ohms?), and any feed-point impedance above that represents loss. In the L-match equation, we know that the lower the feedpoint resistance, the higher shunt C is required ......i.e. the more C required, the better.

Final question for my info: (perhaps for Roy Lewallen).....
....if I model this on EZNEC with a 1" diameter dipole with radial systems attached at both ends (about 3' spokes), in Free Space with zero loss, and of course about 3.9 MHz, source at center, wouldn't the resistive portion represent the acutal radiation resistance?

Roy Lewallen, W7EL wrote:
"Am I mistaken, but is this not a clear statement that a copper or aluminum shield will block magnetic flux along with explanation of why it happens?"

Yes. And now the rest of the story which I`ve already posted several times.

At the bottom of page 38 in Terman`s 1955 edition;
"It is possible to shield slectrostatic flux WITHOUT simultaneously affecting the magnetic field by surrounding the space to be shielded with a conducting cage that is made in such a way as to provide NO low-resistance path for the flow of eddy currents, while at the same time offering a metallic terminal upon which electrostatic flux can terminate."

I invited readers to look at page 43 in the same book where:
"A grid of wires such as shown in the accompanying figure will provide electrostatic shielding WITHOUT magnetic shielding---."

I also said that similar grids (metal picket fences) were used in AM broadcast stations I`d worked in to eliminate capacitive coupling to the antennas which would otherwise favor harmonics of the broadcast frequency.

W8JI is yet desiring to drive a stake in the heart of the "myth" that E&H fields are separable if even for an instant. He is dead wrong.

The magnetic field alone does quite well in transferring all the wave`s energy through a special transformer which completely bars the electric field. Of course, current in the transformer`s secondary produces a voltage and the E-field is immediately restored.

This is not witchcraft. In free-space the electric field and the magnetic field are repeatedly exchanging all the energy back and forth. It keeps the wave going.

At a short or open on a transmission line energy is not lost. It is merely transferred for an instant into the surviving field.

Similarly, all the energy can be transferred through the electric field with zero magnetic coupling. Imagine two separately shielded coils. Now, use a coupling capacitor to transfer the energy from one coil to the other. Voila! E-field transfer with zero magnetic coupling. It`s no myth. It`s a fact.

Best regards, Richard Harrison, KB5WZI

It is probably because those tuners do not do well with a resonant
antenna. With one legg longer than the other there is more chance
that the antenna will be reactive and make the tuner happier.

Maybe with dipoles, but my SGC has no problems with resonance on my
vertical.

FWIW, the vertical is resonant by itself on 40M and has a relay
switched loading coil for 80M I put in before I got the SGC.

With the loading coil out, the SGC has no problems 80M to 10M.

With the loading coil in, 160M to 20M.

Normal operation is loading coil in for 160M and 80M.

Certainly the E or H field can disappear for part of a cycle. This happens routinely in a transmission line or in free space, as the energy is swapped back and forth between the two components. Tom has never said this is not so. And for whole cycles you can locally change the ratio of E/H, but you cannot separate them. Maxwell's equations show this. And if you do change the ratio of E/H, the normal free space ratio is restored within a small distance.

> The magnetic field alone does quite well in transferring all the wave`s

Yes. And does this restored E field not occupy the space between the winding and the wire grid? If so, how can you tell that the grid has "stopped" the E field if it exists on both sides of the grid?

> This is not witchcraft. In free-space the electric field and the

With this I totally agree. That explanation is related to why you can't
simply remove one component or the other.

It's a myth that there's no magnetic field in the space between a
capacitor's plates.

==========
Talking rotor position feedback ,instead of the traditional potmeter in bridge circuit with analogue meter readout ,you could try a low cost synchro system utilising 2 stepper motors from discarded hard drives , dot-matrix printers or flat bed scanners ,with 1 stepper motor mechanically coupled (either directly or via a reversed rotational reducer) to the rotor ,the other in the shack as a readout device. The circuit I found on the web (via Google)needs 5 wires between the stepper motor coupled to the rotor and the control unit ,located with the other stepper motor in the shack.
The circuit includes 4 TIP120 NPN transistors 2 LM324 dual Opamps and a few diodes and resistors. The stepper motor in the shack could either be provided with a rotating or sliding pointer (the latter from an old 1950-60s radio) , or be mechanically linked to a counter (for example from a discarded tape recorder)

A potential 'recycled components' project.

definition of linear as applied to networks."

Right. From "The Penguin Desk Encyclopedia of Science and Mathematics":

"Linear (algebra) An equation or function of the form ax + by + c = 0
or f(x) = mx +b is called linear because its graph is a line. This has
been generalized to a concept called linear combination, which is the
sum of 2 or more entities with each multiplied by some number (with not
all numbers being 0). Linear combinations of vectors, equations, and
functions are commonly employed."

I think that definition is broad enough to cover the representations I
made in my postings.

Best regards, Richard Harrison, KB5WZI

The skin depth of copper at 60 hertz is supposed to be 8.53mm. That's
too thick to make a practical shield. No wonder they're having problems.

You're right in a certain mathematical sense, but that definition
isn't correct, as Roy pointed out, in defining superposition.

OK, you guys can stop now... wx is improving and i found something more fun to play with anyway.... try this site out:

The links don't mail well, but if you go to this link...
http://local.live.com/?v=2&sp=aN.42.467105_-73.022505_k1ttt_

and then do this....

After the page above displays the road view, in the control pad at the top left click on 'bird's eye'... then wait for it to redraw. Then click on the 'W' on the compass rose to view toward the west which seems to be the closest view of my place. Then click on the big set of buildings in that control panel to zoom in. by this point you won't see the station at all, but in the 'scratch pad' control on the right side click on the 'k1ttt' link and it should swing it around and show you a view of my station looking toward the west. the photo is at least 3 to 4 years old now as you can see the 6 element 20m and 8 element 15m yagi's still up that have been replaced.

Yes. So how does a capacitor between two inductors constitute "E-field transfer with zero magnetic coupling" as you stated?

When did you perform this experiment, Richard? (Perfectly shielding two coils and then coupling them with a capacitor.) And how did you manage to shield them if, as you seem to think, the magnetic fields are capable of penetrating the shield?

Oh my goodness! The critical qualification and definition has been provided
by Roy.
Roy and Richard then proceeded to nail the subject to the proverbial wall.

It is time to pause in grading exams to remind that analytic geometry and
circuit theory are not the same thing. In circuit theory (and practice) a
circuit/network/or-whatever is linear if, and only if, superposition is
satisfied. If superposition is satisfied, then the circuit in question is
linear.

This concept also has utility in some mechanical structures.

In English, it is not uncommon for a word to have quite different meanings
depending on where it is used. We all know this. Even when discussing
active devices such as BJTs and FETs one finds the word "saturation" used
differently depending on the device.

Obviously, large enough signals applied to any network that appears to be
linear with smaller signals will melt same - letting out the smoke that was
placed therein at the factory. Obviously, there are degrees of linearity.
A footnote is always understood to say: such-and-such network is acceptably
linear for signals larger than A and smaller than B.

... thus ends the lesson.

Why would you do that? It's the same as just splitting a single output
from the radio. Depending on spacing and phase you can get of variety of
different radiation patterns. You don't need to split it between two
amps.

I split the output from my radio, lag one 90 degrees, put one in one yagi,
put one in another yagi and get circular polarization.

Hi Mac,

My point may have been on target, but the specifics left an escape for
those quick enough to pick up on it. In fact, I would speculate that
most audio (as do RF) amplifiers exhibit the gain characteristic of
f(x) = y = mx + b
and this is called class AB. When you build an amp employing two of
them in a push-pull configuration the constants b negate each other
and the 2mx remains.

Of course, the push-pull configuration is built to nullify the
distortion of this "linear" curve.

The single power supply Op Amp also suffers from
f(x) = y = mx + b
with the output floating at half the supply voltage - this has got to
be an application killer if it goes straight to the speakers without
removing the b with a capacitor.

Hi Tim,

My electronics skills are fairly good, I have built many projects over the time.
What I was wanting to do, is have a control box in the shack with a readout and left/right controls. And have the provision to also be able to have a PC control it.
I like the Pitch-prop motor, as it is strong, and can be controlled easy.

The way I control it at the moment, is via a 2 voltage system.
The pitch-prop runs at 36volts for full speed, and when I wish to slow it down for small movements, I use a second set of controls at 15volts. Not the best way of doing it, but it works.
I then look out the window and see where it is pointing. I know where N, E, S, W are on my section.

As to price on the parts, I would like to keep it down to around a couple of hundred dollars. :)

Regards and thanks for your input.

If I have a different length on the case of the tuner compared to the
length on the hot terminal, how does that moderate impedance?

It is the selction of length combinations of antennas and of course
length and impedance of feedline that has to be considered.

Since everything considered here so far hasn't been logical, it would
be interesting to find out what SGC actually intends.

Assuming you're speaking of a resonant dipole or verticle, it would seem to me that by doing that you are moving the feedpoint away from the 50 ohm (70 ohm?) feedpoint at the center.... and probably towards a higher impedance feedpoint. Not sure what effect that would have on those autotuners, but perhaps they work better with a bit higher impedance than 50 ohms?

Tom, KA6RUH wrote:
"You`re right in a certain mathematical sense, but that definition isn`t correct as Roy pointed out in defining superposition."

Or in conjugate matching for that matter. The discussion was: Is an antenna a linear device, meaning does it produce amplitude distortion?

Amplitude distortion comes from a nonlinear relation between imput and output. It has nothing to do with has the amplitude grown larger or smaller in the antenna? I think the majority of antennas have an output which is a reasonable approximation in form to their input. That goes for frequencies too. The response won`t be the same for all frequencies, but you`re not likely to find new frequencies on the output of the antenna that aren`t on its input.

Superposition says that when a number of voltages (distributed in any manner throughout a linear network) are applied to the network simultaneously, the current that flows is the sum of the component currents that would flow if the same currents had acted individually.

As Cecil said, nonlinearity produces new frequencies. Good antennas don`t do that, superposition or not.

Best regards, Richard Harrison, KB5WZI

Hey Kevin:

http://www.wescottdesign.com/articles/pidwophd.html
http://www.wescottdesign.com/articles/Friction/friction.html

If you want to control it from a PC I'd suggest that you drive an H bridge from a microprocessor, with a PID controller in there to make it go. The biggest key to making a PID loop without doing a bunch of math is to keep your ambition under control -- if you have to go fast, then you need to delve into theory.

As pointed out, PID control can be tricky -- even though I'm a control systems professional there's a good chance that if I did it rev 1.0 would just use the micro to implement virtual buttons, with feedback control for rev 1.1. You definitely want to make sure all the pieces are working before you close the loop.

Source record: 58966

Icom needs to modernize their thinking and get rid of their "old school" installation guides. Wire radials are the way to go on your sailboat. Not copper foil or wide copper strips, just plain old 14 gauge wire radials. I suggest you read some of the threads about this on the Maritime Mobile Ham Forum from people with real world experience with marine HF installations. You'll find the answers to your questions there:

http://cruisenews.net/cgi-bin/mmham/webbbs_config.pl

>As Cecil said, nonlinearity produces new frequencies. Good antennas >don`t do that, superposition or not.

Hi Richard,

Appeals of authority that are pegged to Cecil are like trying to tread water with a concrete life preserver. Your logic is blighted by a forced conclusion that has nothing to do with the obvious observation that antennas, as transmission lines, are quite evidently non-linear in their characteristic Z. This has been demonstrated and is historic from sources that even Terman's accepts.

Saying that this non-linearity must then reveal (of all things) an amplitude distortion is specious. Demanding that "new frequencies" must exist AND then saying they must be of such-and-such a magnitude to so qualify is a hoot.

This is old ground and has not been answered by you or Cecil. Saying 't'ain't so is not debate.

This might be related to the sometimes heard myth / nonsense that a half wave dipole does not need a 1:1 balun at the feedpoint, but that one leg should be made a little longer than the formula length to compensate for the feedline common mode current.

I don't know the source of this concept, but I hear it from time to time from avid readers, usually introduced with "of course, as everyone knows..." .

Message-ID: <lKOcg.7992$Ar6.7849@trnddc02>
Source record: 58969

Hi Cecil

I'll top post to your question and the other repliers.

I have *NO* thoughts of money transfer. This is not an invention. I merely assembled a set of four dipoles so they'd produce a pattern thats sensitive to RHCP thruout the entire hemisphere. I'd probably even pay to get someone to try building and testing one of these Cross antennas. I just dont know what it is good for except receiving signals from NOAA weather satellites.

The Double Cross does look alot like a Lindenblad. But, the dipoles are tilted more sharply toward vertical.

Cecil, you ask about how this antenna differs from a turnstile. The four dipole Double Cross has a pattern that has a much greater sensitivity to RHCP toward the horizon than the turnstile. it even has sensivity to RHCP at the horizon whereas the Turnstile is linear.

The fundamental concept (Cross concept) is two dipoles crossed at 90 degrees, both tilted from vertical, spaced about 90 degrees and fed in phase. That produces circular polarization toward the horizon in two opposite directions.
The Double Cross, which looks a little like the Lindenblad, is two Cross antennas mounted together. One Cross is fed 90 degrees later than the other.

I have been trying to develop this concept for more than a year and have stumbled on a configuration that really works for receiving NOAA polar orbiting satellite signals.
The GEO community has rejected the double Cross as its being "not perfect". I dont know anyone else who'd have interest in an antenna thats really easy to make and will work even when built somewhat differently from some exact model.

A guy in England has been publishing all the NOAA satellite images I record here in Los Alamitos. The images can be seen at http://www.sattraxuk.com/imagestothewestaptdecoder/daily/index.html

The images on this site begin and end at zero degree elevation of the satellite, independent of the received signal strength. So, the viewer can be assured that the images from this Double Cross are a good indication of the sensitivity of the antenna and the amount of pattern nilling.

I have some text written to try to describe the concept. It is really difficult for me to know if that text is understandable. Nobody has ever asked me to clarify any of it. That is - I get no feedback. I just cant

find anyone interested in my project. Oh, I have located one guy who
thinks the Double Cross has merit. He is Patrik Tast, and lives in Finland.

So, if anyone has interest, or knows of anyone who'd like more info on the
Double Cross concept, I'd sure like to share this with them.

Thanks for the interest
Jerry

Depends--, if in phase, Both INPUT, and OUTPUT,
would add (double power, if SAME power on both,
Also would add, if 180 degrees OUT of Phase, both
Input, and Output. And this would be the same as
with Push-Pull amp (both input, and output). but
if In Phase, on input, and OUT of Phase, on
Output,or vice versa, theoretically, would result
in 0 Output. And, if in different phases, probably
would make a great interference source!!!

You mean the "Maritime" mis information forum? Looks like some real
world BS artists on there.

Would you make those radials on the boat resonant or not?
If resonant, how would you know?

How much more inductance would a ground wire have than copper foil.

Get a grip dude, that is the way sales work, it starts at a certain time and ends at a certain. That time may not be on the schedule you like, oh well, that is what being the guy setting up the sale is all about. Don't like it, make your own product, market it, set up a sale and then let folks who want the special price a day or two later have it, it will be your business and you can run it any way you like.

Jeeze, I hate whiners!!!!

There exist transmission lines with a changing Z0 along their
lengths. Those transmission lines are linear systems.

I wonder how the gurus 'splain the different behavior of vertical vs. horizontally polarized antennas, where E field determines the way signals reflect and form the pattern. If E and H fields are so "inseparable" there should be no difference, right?

They are ignoring behavior of E and H fields within the near field of antennas and workings of the shield.

Another example of shield's performance was when I had small shielded loop next to the Beverage. The combination gave better S/N performance and better signal levels than each of them alone. Again, shield performing shielding function in the vicinity of near field of both antennas. Loops were tunable and performing as an antenna, shield was shielding from the near by interference and providing symmetry. FACTS - verifiable not subject to wild speculations about current crawling around the edge to inside of tubing, or antenna inside of electrostatic shield quitting to work as antenna because of "W8JI shield is antenna teachings".

Glad you got a kick out of that. It is not original.

In analog microwave systems, often an baseband intermod monitor is used to alarm the operator that nonlinearity has arrived in his system. New frequencies have appeared and have reached a preset arbitrary amplitude sufficient to trigger an alarm. Nothing is perfect so there will always be some intermod. This requires setting a level of these intermod products which will trigger the alarm. This is a standard procedure.

Best regards, Richard Harrison, KB5WZI

I would assume the following: If you use a splitter with an equal length of coax to the two amps, you would be able to get 100 watts out from the radio to be 50 watts into each amp. I would suspect that you would have double the power out to the antenna assuming you used the same length of coax from the amps to the antenna.

Of course, you have to deal with impedance problems with the splitting of the coax, for example, two 50 ohm cables would result in 25 ohms to the amps. Not good. then the two 50 ohm outputs from the amps would result in 100 ohms to the antenna, not good again....

Hi Richard,

All that was missing from your response was the chuckle, and the number at which distortion begins.

How is it if you are not laughing, that neither are you illuminating to this specific point that is presumable a serious issue? Such a shortfall doesn't inspire much confidence in your logic, which perhaps sank with that concrete life jacket.

C'mon, is 10% distortion to be mandated as linear, and 11% distortion non-linear? Need we push this to Cecil's Limit of perception - ï¿½59%?

Choose your own numbers, or find a true authority to quote a quantitative response.

Were you interested in a field coaxial to the axis of the line, or one
that is transverse? Perhaps I could get my assistant, Beaker, to run
some tests for us. He sometimes get a little, ah, involved with his
experiments, though, so it may take some time.

Regards,
Bunsen

I believe this idea has already been done and used at major airports for
VHF communication. The ones I have seen have 4 dipoles on stalks, and
each is 45 degrees from horizontal. They are used for aircraft in closs
proximity to the field where polarization is unpredictable as craft
enter, leave, and cross over the strip.

Well, I don't have personal experience with this. There is a chapter in the ARRL antenna book, and it basically agrees with ICOM. As to radials - two comments. First - how do you make sure that they don't get in the way. And that RF currents won't be a hazard to people. Second - there are plenty of wires on a yacht. How do the wires know whether or not they are supposed to act as radials?

If there is a better alternative to the traditional backstay using seawater as ground, it might be the vertical dipole. Feeding would be tricky, but for single band operation, you could probably feed it like a J-Pole. I don't see how to make a multiband variant. And you get the high voltage points close to the deck, which doesn't sound like a good idea in a damp and salty environment.

There are also people who hoist a horizontal dipole when needed. OK for recreational radio, not if you need to be able to communicate in rough weather.

Of course, square riggers are beautiful, and you could use the yard-arms as a stacked yagi.

May be they want the impedance on the second harmonic to be less
exciting.

If there is a length of lossy feedline between my resonant 80 m
antenna and the tuner, and I try tuning up on 40 m, I won't fry my
tuner. But if the tuner is at the feedpoint, the voltage gets extremely
high.

> should be no difference, right?

The E and H fields are at right angles to each other. The E field is
the field used to define polarization. A "vertical" antenna has a
vertical E field. It has a horizontal H field.

The E field is higher impedance, and easily "shorted" by the earth.
When it goes away so does the H field. This is why a vertically
polarized wave (vertical electric field) has good ground wave
propagation and a horizontally polarized wave has no useful ground
wave.

This is the very reason noise that propagates along the earth any
distance is mostly vertically polarized.

> They are ignoring behavior of E and H fields within the near field of

No, they understand fine. What most people are saying here fits
perfectly with how everything works.

> antenna inside of electrostatic shield quitting to work as antenna because
> of "W8JI shield is antenna teachings".

Nobody has said a change in antenna design or construction can't cause
a change in performance. The problem is you are trying to tell us is
the "magnetic" portion of time-varying fields can penetrate the wall of
a metal tube. That is NOT true when the wall is a few skin depths
thick. Nothing can go through, neither the time-varying electric nor
magnetic fields. The gap is the feedpoint, the wire inside the tube
simply a coupling mechanism, and the outside of the tube is the actual
antenna. It can't be any other way.

This is something core to how many basic simple things work. This is
the reason a screen room works, why an aluminum can shields IF or RF
coils, how a shield on a radio works, why coaxial cables act like they

do, and so on.

This is why an ungrounded solid metal plate placed between the axis of two coils diverts the flux. This coupling is why, if we measure the inductance and Q of a short length of concentric conductors, the center conductor has more inductance and significantly less Q than the outer conductor.

It's a large part of why everything works as it does for RF. It's very important we understand it, otherwise we create all types of bad science.

Hi BKR

That airport antenna is probably a Lindenblad. It has a serious "lack of
sensitivity" toward zenith. That "null straight up" isnt important at an
airport.
I submit to you that, although this Cross concept is basic and simple,
nobody has yet documented *anything* on it. The Quadrafilar Helix has the
same general pattern characteristics as the Cross, but the Helix is alot
more difficult for me to build and understand. In addition, the Cross can
be made to have considerably more sensitivity toward the horizon than the
Quad Helix.

Curious wrote:
"Will the output of two amplifiers add together in directions where the signal is in phase, or will it act like two different signals and therefore interfere with each other?"

For stereo?

The signals are coherent from two amplifiers or from one.

Two close antennas fed the same signal in the same phase generally add broadside to the plane containing the antennas and cancel at right angles to the lobes containing the added signals.

See page 91 of Kraus` 3rd efition of "Antennas" for: "Two Isotropic Point Sources of the Same Amplitude and Phase."

Another example is the pair af CB antennas used by truckers, one on either side of the truck cab, to reinforce the signal fore and aft of the truck.

The 1/2-wave dipole is another example. Its two elements have the same cuerrent amplitude and direction. Its lobes are broadside and its nulls are at right angles off the tips of the elements.

Best regards, Richard Harrison, KB5WZI

Jerry, can you post a photo on a webpage somewhere?

I think I get it... a single cross is like the driven elements of a circularly polarized crossed yagi, the kind where you get the 90 degree phasing by physical staggering of the elements.

Since it has no reflectors or directors, it's bidirectional. If you cross two Crosses and feed them 90 degrees out of phase you get a more-or-less omnidirectional azimuth pattern.

It is a pair of crossed dipoles fed as a turnstile.

I personally would probably still call it a Lindenblad, but maybe the phasing is different on the Lindenblad.. I think they're phased the same way, though.

Stick up a picture, if you can, or email to me... I'd like to see the construction in case I'm missing something.

One thought of interest is that the phasing for a phased
antenna system might be done at the input of one of the
amps, rather than having to manage high power. But I
wonder if two separate amps could maintain coherency
under all conditions of supply voltage, temperature,
humidity, etc.

Not that it means anything, but the linearity requirement is met when
b = 0, which, of course, is a subset of the family of equations of the
form y = mx + b.

I was thinking along the same lines as Jon, LA4RT when I posted my comment... using an 80m dipole on 40m, maybe you want to move the feedpoint away from the current node.

How about this. If you make one leg 5% longer than the other: The length of leg 1 is L, the length of leg 2 is 1.05L. What do you need to have an integer number of half wavelengths on each side of the feedpoint? (This is the only time you can get a mid element current node, right?)

L=m*lambda/2
1.05L=n*lambda/2

=> 1.05(m*lambda/2)=n*lambda/2

The lowest integers that satisfy this: n/m = 105/100 = 21/20.

So until you hit 21 halfwaves on one side and 20 halfwaves on the other, I think you don't have a current node at the feedpoint.

Is this desirable? I think it probably is, but I am not a tuner expert.

73,
Dan

A good target number for antenna linearity would be one that does not limit system dynamic range. Our best receivers have a dynamic range of around 120 dB as measured by the minimum discernable signal on the low end, and the point where two-tone third order distortion products are detectable on the high end.

140 dB seems reasonable for an antenna and would theoretically be measured the same way as receiver dynamic range, though setting up a noise-free environment, and coupling large distortion-free signals to a test antenna is a challenge, and is probably one reason we don't see these measurements. The other reason is that there is good evidence that a properly built antenna does not limit system dynamic range. That is, it is very linear in the superposition sense.

By the way, generating new frequencies is not necessarily a violation of superposition (though it usually is). Consider a system undergoing a constant Doppler shift.

Hi Dan

The Lindenblad is quite alot different than the Cross. Perhaps my objection to having the Cross being considered to be a version of the Lindenblad is subjective. But, the two antennas are significantly different from each other.

The Cross is not one particular antenna with exact dimensions. The Cross is more a concept. When two Cross antennas are nested together, they can be phased to provide sensitivity to circular polarized signals thruout the hemisphere and have good sensitivity toward the horizon.

If reasonable control applies, it works.

I built a rat-race, hybrid-ring, diplexer to parallel two identical shortwave broadcast transmitters. They were fed from the same RF oscillator and from the same audio source. Both were adjusted for nearly 100% modulation. The pair produced nearly 100 KW, fully modulated into the same antenna. It worked fine. No jerking around and little unbalanced energy dissipated into the dummy load. This was no sweat for the antennas which worked with our 100 KW transmitters every day. This is what you need to do when frequency shortages become acute.

The votages in the transmitters were regulated by Sola transformers which had been shipped to us as 60 Hz transformers but reresonated on site for 50 Hz which was our European supply frequency.

Best regards, Richard Harrison, KB5WZI

>transfer with zero magnetic coupling" as you stated?

Hi All,

Really, this contretemps seems to be over a matter of scale and
application.

Ramo, Whinnery, and Van Duzer make clear distinctions between mutual
couplings and radiative couplings. Most of the discussion in this and
related threads appear to discard these distinctions.

Richard's application of screened air linked couplers and using the
illustration of power transformers is found in "Fields and Waves..."
by these authors:
"Where there is a component of the electric field in phase with
the current, the integral of the electric field cannot be
considered either as a pure "capacitive" or "inductive" voltage
drop since there will be real energy transfer (radiation) from
these terms."
Richard's applications and illustrations do not push this boundary. In
fact, Ramo et. al distinctly offer the case of "electrostatic
shielding" and clearly support the separation of magnetic and electric
flux (fields). And so as to anticipate the conundrum of the "static"
in electrostatic, the authors show no issue. However, they do provide
a rational warning:
"It often happens that electrodes, although grounded
for direct current, may be effectively insulated or floating
at radio frequencies because of impedance in the grounding
leads. In such cases the new electrodes do not accomplish
their shielding purposes but may in fact increase capacitive
coupling."

Insofar as Yuri's complaint, it is an ego trip that wholly ignores the scales of wavelength, the application of materials, the nature of balance, and the misapplication of mutual coupling to explain far field effects. In short, he has been bitten by the "lumped vs. distributed" distinction once again. The only saving grace of his argument may be found in that there are two forms of the "shielded dipole" where one supports Tom's claim, and the other support's Yuri's.

Unfortunately, as correct as Richard's examples are, they too are misapplied to the "shielded dipole." The "shielded dipole" may be small in relation to wavelength, but its response mechanism is NOT found by using mutual coupling math, but rather through radiation math.

I've done it with a pair of 160 watt Mirage amps on 2-meters.

Many years ago I owned one of the first high power (bout 600W) solid state 2-meter amps. Inside it was just several amps in parallel on the same, large circuit board. Capacitance on the input adjusted the phase and you basically tuned it for max. The output was the same way. However it used the earlier bi-polar transistors (this would have been in the late 70's) and there was quite a bit of interaction between input and output.

I picked up a pair of 160 watt Mirage amps off e-Bay. With the Mirage amps I disabled the internal keying on one and set it up as a slave to the other. If you leave the internal keying on in both they will cycle back and forth which will have some rather undesirable effects. I used a C3i power divider/combiner on the input and another on the outputs. I tuned them up pretty much as I did the old amp and ended up with over 300 W out.

This approach really need amps of the same make, model, and age (no
design changes) to work the best but it will work. OTOH if starting
from new it's no more expensive to go out and purchase one of the new
380 watt TE amps. The high power Mirage is a bit more expensive.

Can you direct me to where in the text they do so? All I've found is a short section (5.28) on "Electrostatic Shielding" where they explain that introducing a grounded conductor near two others will reduce the capacitive coupling between them. Obviously this will alter the local E/H ratio, but in no way does it allow an E or H field to exist independently, even locally, let alone at any distance.

Once you reach the point of copying subconsciously it's just like
talking.

>programs. Most don't handle noise very well. Once I hit 55-60 wpm
>on a paddle, I was stretching the limits. Past that, and it was pretty

I made 40 but never higher than that. OTOH back then I was spending
one to two hours a day on CW.

>dang ugly... Slopsville. The keyboards could kick back and type
>about any CW speed with perfect sending. A decent typist can go
>over 100 wpm+.

There are few people who can type that fast. However on CW you type
your response while listening to the other station so the transmission
speed can be well above your typing speed.

I can count on the fingers of one hand the number of people I've met
in school and industry who could even approach that 100 wpm.
The old electric portables used to jam the keys at much over 60 while
the "selectric" could go a fair amount faster. When in college my
daughter wore out one of those and she could out type it.

I shouldn't count the college classes when I was a GA teaching the
intro to CS, out of 195 students I only had about 10 that could type
and none that could keep up with me.

Unfortunately, age is catching up and I've had to slow down with the keyer and I'm not nearly as fast with the keyboard as I was. I can probably still type at 40 wpm after mistakes are taken out. 60 if I don't go back and correct.

There is another potential problem if feeding two amps to two antennas that
are reasonably close: RF from one antenna is induced into the other antenna,
gets fed into the amp and causes some interference (mixing ?) that shows up
as a raspy signal.
Tried it, and heard it on another station attempting the same setup.
It seems that it would be easier to control the phasing at the input of the
PAs, but the above effect messes it up, unless antennas are widely separated
and they do not "feed" each other setup.
So, it appears that it is better to use one bigger amp and use proper
phasing to feed the two or more antennas.

Joe,
Another concern (though I have no experience with roofs, just autos) is the
intermitent contact (as opposed to a rectifying junction, as Richard points
out) that is possible. If there are joints that can make and break, say in
the wind, you may have noise generated. Chain-link fences would be
susceptable to this as well. Wether or not it produces noise in your
receiver, I would think, is rather unlikely, unless you were somewhere near
a broadcast station or another ham for reasons described next.
Interestingly enough, if the transmit antenna is reasonably close to the
roof, it would manifest itself as noise on your *transmitted* signal also,
but probably low enough such that those listeming to you would hear it.
I had some experience with this phenomenon with things like trunk lids and
motorcycle seat springs causing noise in the 150 MHz car phones of the past.
The transmitter illuminated the noisy joint and the czarrier was literally
modulated by this. The near-by noisy joint can be considered to be a
parasitic element in the transmit antenna system and therefore produce
low-level, but annoying amounts of noise modulation. It appears as

sidebands on the transmitter which duplicate the noise of the joint. This in turn was wide-band exnogh to extend over to the receive frequency. Because it was full duplex and both Tx and Rx were on the same antenna, it was a noise problem in the receiver. Also why I believe it is a bad idea to use a chain link fence as a counterpoise.

Hi Roy,

Article 5.12 "Circuit Concepts at High Frequencies or Large
Dimensions"

Figure 5.28(a) shows a complete shielding. Of course this is entirely
electric, and arguably magnetic. However, magnetic flux can penetrate
thin shields, electric flux cannot.

This is part and parcel to the world of isolated and shielded
circuits. The electrostatic shields are as effective as they are
complete in their coverage. Their contribution is measured in mutual
capacitance between the two points being isolated. With a drain wire
to ground, and a low enough Z in that wire, then that mutual
capacitance tends towards zero (however, near zero is a matter of
degree as I've offered in past discussion).

Figure 5.28(a) shielding is quite common in medical circuit design,
and mutual capacitance does equal zero; and yet signals and power pass
in and out through magnetic coupling. Isolated relays are a very
compelling example of magnetic transparency in the face of total
electric shielding.

Magnetic shielding operates through reflection or dissipation
(absorption loss due to eddy currents). This loss is a function of
permeability ï¿½. Unfortunately, permeability declines with increasing
frequency, and with declining field strength. Basically, all metals
exhibit the same characteristic ï¿½ above VLF; hence any appeal to
"magnetic materials" used to build antennas is specious.

This is not to say the magnetic shield is ineffective, merely derated seriously from what might be gleaned through poor inference by reading ï¿½ values from tables.

However, it is quite obvious that transformer inter stage shielding and the faraday shield found in AM transmitters is not seeking to optimize this attenuation, far from it. Thus the degree in isolation is found in the ratio of the mutual capacitance between the two points before and after shielding; and the attenuation in magnetic flux induction introduced between the two circuits after shielding.

Returning to Ramo, et. al, the introduction of a partial shield. Figure 5.28(c) is effective insofar as its ability to reduce mutual capacitance.

Richard Clark wrote:
"Your explanation sounds like you are practicing psychaitry, not technoligy."

I think quantification is valuable if the measured value is accurate and if the value makes a difference.

Antennas are used with transmitters of megawatts of power. These have limitations by regulations on maximum noise and harmonic content. It depends on the jurisdiction, but maximum noise and distortion must be at least 50 dB below the fully modulated level in some locales. I`ve often used the H.P. noise and distortion analyzer to measure off the air to be sure we complied with the regulation. It never occurred to me that our antenna system had a part in noise and distortion production. I expected curvature in a tube`s characteristics or a failed component to cause a rise in noise and distortion. Not once do I recall our antenna system causing distortion anywhere except in the edges of pattern nulls. This is normal.

Receiving antennas on the other hand deliver a satisfactory signal having only microwatts of power. As one responder noted the dynamic range is enormous. This is not really an issue for concern among amateurs. Antennas are in general distortion free.

Best regards, RIchard Harrison, KB5WZI

Hi Richard,

So in this exception, I would make one compelling correlation to your own observation. That distortion of the pattern was a product of non-linear behavior in the characteristic Z of the antenna. That alone seems to be evident. It happens so frequently that we need complex tools (NEC) to juggle the outcome.

We have non-linear behavior, distortion, and it didn't demand harmonics, did it? Such non-linearity AND distortion were in all likelihood trivial, and yet it was noticeable. Now, if no one complained about pattern nulls being lost, would the non-linearity go away? ;-)

Cecil would shrug off 59% worth of distortion to define it linear.

Perhaps a more realistic concern would be lightning protection. A friend down in Fl had just installed a metal roof on his shop just 3 days prior to it being struck by lightning. Seems the worst damage was a softball size hole burned in the metal. First installing lightning rods and associated grounds would provide a good begining to bonding of a metal roof.

> electric, and arguably magnetic. However, magnetic flux can penetrate
> thin shields, electric flux cannot.

Only when the shield is thin compared to the skin depth.
When the shield is thick relative to skin depth nothing gets through.

This is very easy to prove. I have been making measurements of a ~ .032 inch thick copper wall and with 0dB reference on a small resonant pick up loop my analyzer is in the noise (-90dB) on the side directly opposite that loop.

The same is true for a direct soldered connection to the wall on each opposite side.

One inch to the side on the same side levels are -10dB. That would be a two inch long path shorted by the copper the entire way. Go to the direct opposite side through only .032 thick copper and levels are not even detectable.

> This is part and parcel to the world of isolated and shielded
> circuits. The electrostatic shields are as effective as they are
> complete in their coverage. Their contribution is measured in mutual
> capacitance between the two points being isolated.

I don't have that reference and so cannot see that shield, but the only thing the shield can do is reduce field impedance by changing the ratio of electric to magnetic fields. In order to take either one to zero the other must also be at zero.

I think the confusion comes from misapplying a grid forming a shunt capacitance to reduce direct capacitance between two objects (forming a "T" divider) to the shielded loop antenna or shielded link.

Consider a loop of any size, even a link in a tank coil. That conductor has a field impedance and radiation characteristics largely set by the diameter of the coil.

Once we put a wall around that conductor more than a few skin depths thick NOTHING goes through that wall. The "shield" actually becomes the coupling coil, the link inside simply develops a voltage across the shield to drive that external coil. Both electric and magnetic fields are present on the outer wall of the shield, and while they may be modified by shield balance they really are not much different than we had with just the inner conductor alone. We really just change the balance.

With the grid, we have substantial air gap segmenting the "wall". Naturally the coupling mechanism is different than we have with a solid wall. We, in effect, have dozens of long gaps.

Each conductor in that grid is indeed excited by the magnetic and electric fields, and each conductor has a potential difference across area and a current flowing. Part of the field, both electric and magnetic, leaks through. Part is reradiated by the currents and voltages in the grid.

I think at some point of time MRT or Dave Saloff patented a right angle grid of two layers with opposing ends in each adjacent conductor in each layer grounded that I designed. The idea was to more evenly distribute the fields and prevent "hot spots". This was for a medical application.

Rest assured this applicator produced both time-varying electric and magnetic fields, but the balance was so much improved tuning was more stable. The improved balance and evenly distributed field meant the feedline did not radiate any significant amount when brought near the patient, unlike a regular multiple turn loop.

I still have some prototype applicators here, as well as the field measurements required by the FDA. The applicator actually had to match with lowest return loss into the buttocks of an average size 30 year old female.

Hi Tom,

There are too many contra-examples too sustain your point. What you
are talking about is radiation, this does not account for common
induction that occurs on the very short scales I've offered.

My father was NY state champ at over 100 wpm on a manual typewriter in about 1940. I always figured Bucky the milkman must have been my real father, since I was at 15 wpm before typing class, and 12 after a year of it. I still type with 4 fingers, and have to use my eyes to figure where they should go. And I have typed for a living for the last 30+ years. :)

Well, the expert, or should I say, the new GURU, has spoken. He seems
to know all about this complex subject.

I know I will never try this again, as my previous efforts, which seemed
to work, could not possibly have done so. Obviously Wilkenson hybrids
are useless, likewise any ring hybrids, and all other methods of
splitting/combining a transmitter feed.

Sorry guys, they won't work. Yuri said so.

Hi Dan

Yeah, I can show you exactly how I built a Double Cross for receiving NOAA satellite signals. A buddy of mine has chosen to publish everything I send him.

http://213.250.83.83/~jerry/index.html

There is probably too much data on that site. The excess info and pictures may get confusing.

Since you read this "antennas group", I'll assume that you may know as much or more about antennas as I do. I dont claim to know *the best* configuration of the Cross concept for APT reception. I do suggest that four dipoles mounted so they are tilted slightly from vertical and spaced so the diagonal dipoles are about 1/6th wave separated. can be easily fed to provide RHCP toward the horizon and toward zenith. In the web site
http://www.amsat.org/amsat/articles/w6shp/lindy.html
The Lindenblad is described as an array of four dipoles tilted 30 degrees from Horizontal and spaced 0.3 wave and all fed in phase.

The Lindenblad has a deep null straight up. The Double Cross has no null anywhere in the hemisphere.

Thanks for the interest in the Cross. If you have any situation where this hemispheric coverage with sensitivity to circular polarization, I'd be interested in helping you design a Double Cross. All the Double Cross antennas I've made seem to work well for receiving signals from the NOAA polar orbiting satellites.

Jerry

Antennas are in general distortion free.

Yes, but "bad times" can make them non-linear. Consider the bolted joints
that get
corroded and semi-conductive over time, with rain and temperature changes to
help.

Nearby RF sources can generate distortion products in my antennas if I
haven't
kept up my maintenance.

It's mostly a problem if you are running two or more rigs at the same
time. Your 2M packet rig could interfere with your 2M ragchew.

The Navy, for whom I work, bonds (or isolates) everything topside for
exactly the reason you stated. The intermittent contacts are noise
generators. The tools for detecting some troublesome items are a rubber
mallet and a pair of handhelds. One guy in radio transmits a carrier,
while listening on a nearby freq. If he hears anything, he grabs his
handheld and barks, "What was that you just tapped on?" Primitive but
functional. Every spark, no matter how small, is an RF generator. Chains
are awful. We hate chains.

Jerry,

OK, I'm getting more of an idea of the differences between the Lindy
and the Double Cross.

Well, I'm not particularly satellite-active right now, but I might have
to try one out sometime.

Keep up the experimentation... it would be cool to make a NEC model of
the thing, but I have EZNEC, currently without circular polarization
ability, so I can't do it.

I should try the Wefax thing sometime... that's pretty neat.

I think I have a TNC that can RX such transmissions.

Yes. Depending on the single-radiator pattern shapes and installation geometry, mutual coupling between two adjacent antennas of the same polarization, and cut for the same frequency can be -10 dB or less. An "apparent reflected power" of -10 dBc = 1.92 SWR to each tx, plus whatever SWR each antenna system has to the tx hardwired to it.

This performance may be OK for amateur radio, but not for broadcast stations. To avoid this situation, broadcast system designs using several r-f amplifiers combine the amplifier outputs to drive the antenna system from a single set of terminals.

The antenna system design itself provides omnidirectional or directional coverage in the horizontal plane as needed, but it is always fed from a single set of terminals.

Aaaah, here chimes in another W8JI worshipper, who can not read posting,
understand it and reply intelligently, but resorting to snotty, personal,
pathetic remarks. You may have noticed that I do not take crap and respond
in kind.

> I know I will never try this again, as my previous efforts, which seemed
> to work, could not possibly have done so. Obviously Wilkenson hybrids are
> useless, likewise any ring hybrids, and all other methods of
> splitting/combining a transmitter feed.
>

READ IT AGAIN carefully, I have not say that "Wilkenson" (learn spelling)
hybrid would not work or anything about dividing - combining signals. I have
noted that if TWO amplifiers are fed into TWO (separate) antennas that are
in close proximity (mutual impedance at play) then the signals from the one
antenna get picked up by the other antenna, fed back to the amplifiers and
cause distortion that manifests itself as a raspy CW tone or SSB modulation
on the air. I also mentioned that possible remedy is to separate the
antennas in a such way that there is no significant signal feedback between
them. Like you could have one amp feeding EU antenna, and another one
feeding SA antenna, separated properly, fed from the same TX and using
splitters, to satisfy the impedance match between the TX and AMPS.

> Sorry guys, they won't work. Yuri said so.
>

I didn't say such a thing, I brought up potential problem to situation (feeding 2 amps to 2 ants) in question and offered possible solution. I did not even mention hybrids or ways of phasing the gizmos, where did you get it from, private conversation with the other Tom? You got the GURU thing mixed up. I do not play GURU on Internet by publicizing "wisdom pages" like W8JI does, I would chime in with help when I see the need for it (and have time) or when I see gross crap being paraded as "gospel".
Thank you for showing your feathers and displaying your depth!
Your picture would look pretier if you engaged in technical, civil discussions, rather than that "W8JI thing".

Not sure of the context but ideally at a voltage node in an
unterminated transmission line, the E-field is very close to
zero while almost all of the EM energy exists in the H-field.
According to "Optics", by Hecht, the same thing can
happen in free space with light waves.

Not at all sireee!
This was response to W8JI baloney and to provide place for some explanation and graphics, which reflectors and NGs do not afford.
If you followed my publishing career since 1958 and behind the Iron Curtain, and if you knew me, you would find that I keep most of the stuff to myself, even some groundbreaking ideas or inventions, I use them to my advantage to gear up and operate in the contests, where I enjoy beating the competition, there, stripped of pompous drivel and boasting. There, results are expressed as points, placement in the ladder or record tables.

It is the most misleading junk science, that when I see it, I get stirred up enough to respond with what I know to be the right or backed up by reality. So if you look at my web site and see the "coil thing" and comparing this to W8JI "guru thing" I wonder about your judgement. I am trying to be civil and stay with technical discussions, but if someone resorts to personal attacks and crap, I do not take it laying down with my mouth open.

I think you would be better off also to stick to matter o'fact technical discussions rather than trying to display your literary talents of poking people in the eyes.

I could care less what youze guyze here theoretize about or fight for number one wize guy on the totem pole, or who you worship.
I enjoy ham radio as a means to keep in step with technology, enjoy contacting and beating people in the contests and to keep my mind sharp.

Last thing I "enjoy" is arguing with an idiot or participate in a pissing contests with skunks. I hope I 'splained myself poetically enuf!

So I will not try to be the "last one standing - right" as W8JI philosophy is. You can have it - argue all you want. I posted what I know, have seen, am convinced of and can prove it. You can "figure" it all you want. I said, described my piece, the reality is the judge and not some scientwists!

Have nice Memorial Day, remember those who gave their lives so you can live in a freedom, otherwise sucks! Been there, paid with lives of dear ones!

Hi Yuri,

More surprising are most of those devotional writings come from a
heretic to your kool-aid chapter. Selective editing sure brings out
the hosannas though.

Has anyone tried the Ramsey "Signal Magnet Antenna" as a 160 or 80 meter antenna? It is a ferrite rod (looks about 8 inches long) with a preamp installed next to the rod. The rod would be installed remotely from the control box, using an RG59 connection. It was designed for broadcast band use, but can be tuned elsewhere.

BTW, is there a known problem with the eham site?

a note here, the SGC, SEA, and Motorola tuners were all deisgned to
feed unbalanced antennas. There were a few hardy souls who took two
SEA 1612B's and made one slave to the CPU of the other, so as to
make a balanced type tuner, with a bit of success, but the firmware
was never designed to do this and it was a hack to be sure.

> When used to center-feed a dipole, making the ground-side leg longer
> than the hot-side leg increases the capacitance to ground on that side

I have a few 1612B's that drive dipole antennas with vairous feed systems
scattered around Alaska, and they seem to funcntion at least as good as
an unbalanced Marconi type antenna in the same fixed location. The
whole point of trying this was to be able to ignore the RF Ground at
these fixed sites, which mostly were on Glacal Till, which is just
about the same as a sheet of Glass, as far as RF is concerened. When
I was first entertaining this idea, I spent a lot of time with Bill
Forgey and Mark Johnson @ SEA talking about the possibilites, and we
came to the conclusion that I would work, if one took the 50Ohm Feedline,
DC Power Lines, and Tuned Anunciator Lines and wound the Trifiler on
a big Torriod to isolate the tuner from the the radio.

There are a few that tried to use a 1:1 Balun across the output of the
tuner to ground, and then feeding a balanced feedline/antenna system,
with some sucess, but some of the better MF/HF Antenna Designers that
I consulted, were dubious if that approch was a real valid system.

> it to work, but in my installation it's finicky in the extreme about
> its ability to match a wire.
>

All of the autotuners of this type have serious limitations, especially
as they approch the 1/2Wave point of the physical antenna, where
impedances ramp up to infinite. All of them use the Phase, Frequency,
and Forward/Reverse Power, type sensers to let the cpu know what is
going on as it ripples thru the Fixed L and C in Binary Increments.
Some of the firmware actually has some smarts built in, but most
use the same basic algorythem the Sillbe wrote for the original Motorola
Micom Tuners.

Bruce in alaska who was around the BIZ, when all this was going on....

Radials are the WORST type of RF Ground for ANY MF/HF Marine Antenna
System. Anyone who has any sense at all can understand this, just
thinbk about it. First, they have to be very long when dealing with
frequencies below 4 Mhz, and unless you have a BIG vessel, you don't
have room for 1/4 wave radials. Second, Radials need to be resonant
to do any good, and that limits them to one or two frequencies, where
Marine Radios need to have antennas that can operate on many Bands,
which is why non-resonate, low impedance, RF Grounds, are used
by most all Commercial Marine Antenna Systems. I suggest that you
go out and get 30 Years of Commercial Marine Radio Installation and
Operation Experience, and then come back and explain it all to us,
again.......in detail.....if you live that long....

Me been there, done that......

Last week I posted a brainteaser over on qrz.com. Nobody figured
it out. I wonder how many on r.r.a.a can figure it out.

Given: A one second long lossless transmission line with a
steady-state forward power of 200 watts and a reflected power
of 100 watts. How many joules are contained in that feedline?

I had Beaker set up an experiment to test this, and after he put out the fire he started in his hair when the first load he tried melted a hole in the lab bench, he finally got it set up right. He determined that the mass of the line increased by about 3.338 femtograms when powered as compared with it unpowered. We're now looking into what to do with the line, as it's cluttering up the lab, and we're open to suggestions.

Regards,
Bunsen

As others have pointed out in other contexts, it is more useful to think
about an HF "radial" on a boat as the "other half" of a vertical dipole,
rather than as an "RF ground". Even with substantial asymmetry (which is

almost a necessity, given the proximity of the horizontal "radial" to the sea), most autotuners can match an off-center-fed, L-shaped configuration easily. It is not necessary that the horizontal "radial" be resonant for good performance.

Disregarding the balanced, center-fed dipole, the most common alternative approaches to a vertical antenna are 1) the use of the sea as a large ground plane, usually with a Dynaplate, and 2) the use of a large conducting surface (traditionally specified as a minimum of 100 square feet) inside the hull. This surface can also be thought of as the other half of an asymmetrical dipole. It is often connected to the sea through under water metal parts such as the keel, in which case it constitutes a kind of hybrid involving both 1 and 2.

Comparative test data on these systems are quite difficult to obtain and virtually all of the information available is anecdotal, rarely reproducible, and often contradictory. Analytical studies of these systems, particularly as applied to fiberglass yachts, are also scarce.

Unless you really know what you are doing, I second Me's advice to find someone with a lot of experience for assistance. Of course, experimentation is a good thing, too.

Good luck.

Chuck

Cecil, W5DXP wrote:
"How many joules are contained in that feedline?"

I`ll speculate that after one second, 200 joules are contained in the forward wave on that line. Then, after two seconds, another 100 joules has been reflected back toward the line feedpoint where it opposes growth of power input to the line. Total joules on the line is 300.

Forward power minus the reflected power equals 100 watts being supplied by the generator to the load with 200 watts forward power and 100 watts reflrcted power in the line.

Best regards, Richard Harrison, KB5WZI

That can be shown to be true by noting that during the
transient buildup to steady-state, 300 joules sourced
by the generator have not yet reached the load. That
remains true until the generator is powered down, i.e.
all during steady-state.

> Forward power minus the reflected power equals 100 watts being supplied

But what about the people who say there's no energy in the
reflected wave? Reckon how they sweep all those joules,
whose energy must be conserved, under the rug? :-)

OK, I'm a bit worried about bringing up this topic given that my search of r.r.a.a. archives has turned up the fact that this has been a very contentious topic in the past... but

GENETIC ANTENNA OPTIMIZATION

There, I got it out.

I'm interested in the possibility of using this kind of search of the space of possible antennas in those situations that we all end up in, you've put the antenna too close to the tower, you're shoehorning it into the attic, or you really really need to mount it on the bumper and not on the roof.

Has anyone written any software that could do this? I guess what I'm imagining is that you input the location and extent of fixed conductors, the tower, the car (yes i know it's hard), the wiring in the walls, whatever, and then you let the computer chew on what particular weird zig-zag of metal will give you the pattern you *want* rather than living with the pattern of an antenna designed without the additional conductors in place.

For attic antennas, you could have a figure of merit based on some combination of minimizing loss and minimizing the currents induced in the fixed conductors. Keep that RF off the house wiring, and the noise off the antenna, while still radiating most of your power?

I guess there was some prior discussion of use of genetic optimization processes to design amateur antennas being of dubious legality because of patents... if this is the case, forget I even posted it.

I could imagine this being of great use to the restricted-space amateur if the code to do it would be tractable and a sensible interface were present.

Roy, you wanna write an EZNEC plugin that takes wires #n to #m and fiddles with them until the far field is within some tolerance of a desired pattern? I bet it would sell...

It's a thought. I'd be interested in what other people think... the word "genetic" could even be dropped if it is a sticking point since I don't really care what particular approach is taken to push the design toward some goal.

The genetic algorithms are recursive. Maybe "recursive" would
be a better term for something that is not alive.

There are already some general-purpose genetic-optimization packages
freely available in languages such as Perl.

It ought to be possible to write a set of wrappers which uses such a
package to manage the "genome" of an antenna-design space being
searched, convert each individual genome to a NEC configuration, run
NEC2 or a similar package, and extract the results.

>For attic antennas, you could have a figure of merit based on some
>combination of minimizing loss and minimizing the currents induced in
>the fixed conductors. Keep that RF off the house wiring, and the noise
>off the antenna, while still radiating most of your power?

I'm by no means an expert in this field, but based on some reading I
did a month or so ago I have a feeling that a single figure-of-merit
is not necessarily the right way to go. The search process can end up
being extremely (and perhaps excessively) sensitive to small changes
in the weighting factors.

Rather, most people these days seem to approach such problems from the
point of view of Pareto optimality. That is, there are a number of
figures of merit, which evaluate or rate different (and usually
independent) objectives. A possible solution is Pareto-optimal if
any change you make in it results in at least one figure of merit
getting worse.

Optimization system based on Pareto optimality maintain a population
of solutions (many or most of which are Pareto-optimal) and then
generate new solutions from that set (possibly by "genetic" means).

You end up with a bunch of workable Pareto-optimal solutions, and then pick from among them at the end of the process - possibly by applying a final formula to merge the various figures-of-merit for each solution into a final "how good is it?" figure.

Deferring this final merging until the end of the process seems to help keep the search system from prematurely glomming onto what turns out to be a local maximum in the goodness function.

It'd also be a good idea to have some way of evaluating how "brittle" a possible solution is. If even a slight change in one of the parameters causes a previously-optimal solution to become very non-optimal, then it's probably not a good choice for use in an amateur installation.

You might want to look for clusters of Pareto-optimal solutions, and then pick one from near the center of the cluster as being both "representative", and also "robust"... small changes in the parameters wouldn't take you outside of the general area of the cluster.

>I guess there was some prior discussion of use of genetic optimization
>processes to design amateur antennas being of dubious legality because
>of patents... if this is the case, forget I even posted it.

That's certainly an issue. Someone wanting to pursue this might be well advised to do some research into older texts, find out what the state-of-the-art was a couple of decades ago, and base any implementation solely on techniques which were in the public domain back then or which were covered by patents which have since lapsed.

Hi Dan,

Hear the one about the constipated antenna designer?
He worked it out with a smith chart.

GA algorithms in this field are used by those with too much money, or
too much time on their hands, or both.

Experience generally trumps the quality of these computational hungry
products. You can search NASA for its recent GA generated antennas
(offered as a new thread some several months ago). They make nice
modern art designs, but it is arguable the effort was worth the
outcome.

Yes, but the 200 joules in the line was previously sourced
by the generator during the transient state. It's hard to
sweep 200 joules under the reflected power rug.

Although there can be and are exceptions, a publisher generally acquires the copyright from the author prior to publication, so it can reprint as it chooses. But it's also not unusual for the contract to stipulate that the copyright revert back to the author when the publisher is no longer interested (e.g., after the last printing they intend to do has sold out).

First, radials on a boat are not usually better than a good ground to
seawater.
If you do use radials they need to be resonant which means they need
to be ï¿½ wavelength long at each frequency of operation or they need to
be tuned with a loading coil to make them resonant. The reason is that
if they are not resonant you will get little current into them. Your
antenna system will be unbalanced and being that the radials will
usually be closer to other wires etc. on the boat they will couple
into them before they couple to the sea. That will make the tuner coax
and control cables radiators as well, because of the higher impedance
of the radials.

If the radials are mounted in the bottom of the hull right near the
water they have a chance of coupling to the sea. But if you go to that
trouble it is much easier to couple directly to the seawater with some
metal under the boat. (dynaplate, through hulls etc.)

Radials that do not couple the energy to the sea act as part of the antenna. That wouldn't be bad if that radiation went where you wanted it to go but a large part of it will get into all sorts of things on the boat that you don't want it to.

Radials on a boat are different than when laid over earth. When laid over earth there is tight coupling to the earth and length is not important. When they are elevated above earth they need to be resonant in order to work. Short radials do little good in this situation. A boat installation is similar to an elevated installation on land.

I see some guys on the Maritime mis-information forum spouting about using radials on a boat.

You are much better off getting a connection to the sea for your ground. It is one of the best ground planes available. To do so you need a very short ground lead from the tuner to the sea connection. The best way to accomplish that is to mount the tuner down in the hull right next to the sea ground connection within a foot or so. Then run your antenna lead from the tuner to the antenna as much in the clear as you can.

Remember that no matter where the tuner is mounted the antenna starts at the ground connection. If you have a 10 foot lead from the tuners ground connection to the sea water connection that 10 feet will radiate like the antenna. Problem is so will the coax and tuner control lines radiate and couple into all sorts of places you don't want it to.

By placing the tuner at the ground connection you have control over what radiates and what does not.

Copper foil for the ground lead to the tuner makes a lower impedance path than doe's wire. You want the lowest impedance path you can get for the ground lead.

Expanding on my earlier response - For the first two seconds,
the source doesn't know it is looking into an open transmission
line so a 100 watt source would faithfully output 200 joules
into a one second long open circuit transmission line. That
200 joules cannot be destroyed. Is it mere coincidence that
the forward and reflected waves are 100 joules/sec*(one second),
exactly equal to the 200 joules supplied by the source?

Yeah, but the senile old farts still believe they are not only
first responders but that they are on the cutting edge
of technology. Let them wallow in their delusions of how
important ham radio is.

Our "radio" club is more of a social circle. Rarely is anything
technical dicussed, just gossip about other hams. We
meet at Golden Corral. When someone brings their kids along,
the senile old farts start yammering about future hams, and when
is he going to get his ham ticket? Meanwhile, the kids sit
there and eat with iPods stuck in their ears, cell phones in their
hands, and chattering about IM and MySpace.com All of
which may just as well be a foreign language to the delusional
old farts. LOL!

Typical response. Just read what happened in this thread.
Look at what I wrote, look at what you responded.
I am not criticizing, I respond to crap and personal attacks in kind, not very nice, but I do not need to put up with snotty remarks and personal BS.
Looks like hurlers don't like when one responds in kind.
If discussion is about technical matters, I provide help where I can or feel like. If jerk doesn't like it and comes riding high horse, then I get on my horse too, which happened with W8JI (we go way back) and now with you.
I provided my opinion on 2 PAs to 2 ANTs, you twisted it and snapped GURU crap on it, Richard Clark was right behind you. I hate to see you when you are out of your depth. Now you come on with lecture about "crowd having problem with me"?
You discuss technical matters in a civil way, I respond in kind, you pull out snotty crap, and I don't take it. Mark it down and next time if you want do the technical exchange I am open for dialog.
What you want me to do to be "nice"? Accept the "truth" that current along the loading coil is ALWAYS the same, that shield IS the antenna, that electrostatic shield can't possibly work, that antenna is not an antenna?
Where I come from, we fight for truth and if needed give life for it. If you want me to bow to false teachings, or to take crap, look somewhere else.
So you want to try to be nice and discuss the problems with intermods between two PAs feeding two antennas or play W8JI? I can also engage on Wilkinson's hybrids, I use them.
Let's stay with the subjects of this NG and keep the crap for the toilets.

An equation that I leave in my HP calculator interrelates the important
parameters.

T = take-of-angle (up from horizon)
D = distance in Mm (40 Mm is all of the way around the earth)
H = virtual height of ionosphere in km

Calculator is using angles in degrees.
Single hop

Cos(T) / Cos(T + 4.5*D) = 1 + H/6366

F2 H for 40 degrees north is between about 250 and 370.

Wow, got me beat. All I have is an Icom 746 that has been opened up.
Basically transmits from 1-170 Mhz. I do have an Icom 2340H that does the
same. I have several other radios, 2M, 440 that don't merit mentioning.

> with a jouler's brush?

All kidding aside, whatever number of joules of energy are
required to support the forward power and reflected power
is provided by the source during the transient condition
following power up.

If the source power is 100 watts, the forward power is 200
watts, the reflected power is 100 watts, and the load power
is 100 watts, all the joules per second needed to support
that forward and reflected power was supplied by the source
before steady-state was reached. Anything else would violate
the conservation of energy principle.

This is easily proven using a one second long lossless
transmission line as a conceptual training aid for the
uninitiated.

Don't need to. Went to Dayton last
weekend and only ONE-THIRD (1/3)
of the total outdoor flea market spaces
were taken, meaning occupied. Not only
that, I was actually able to park in a lot
at a strip mall just down the road from
the Arena. I have been going to Dayton
since 1980. I've missed going only 4 Years
out of 26. This Year was the absolute
smallest attendance I have ever seen.
This alone should tell you something folks.
I doubt that I'll be going again next Year, if
ever again. Finally do not believe the "official"
attendance figures. They lie thru their teeth
worse than 5 pre-owned auto salesmen.

>>>
>>> Figure 5.28(a) shows a complete shielding. Of course this is entirely
>>> electric, and arguably magnetic. However, magnetic flux can penetrate
>>> thin shields, electric flux cannot.

We've been talking about *time-varying* fields, and must have forgotten to explicitly state that qualification. The figure in question deals with static fields. Time-varying electric flux can indeed penetrate thin shields of finite conductivity, although the E/H ratio within the shield is very small. If a shield could block time-varying electric fields, the time-varying magnetic field which remained would create an electric field. A time-varying magnetic fields creates a time-varying electric field and vice-versa; this is dictated by Maxwell's equations. The answer to question 4.06d in Ramo, et al, "Can a time-varying field of any form exist in space without a corresponding electric field? Can a time-varying electric field exist without the corresponding magnetic field?" is no.

A gapless shield made of a perfect conductor of any thickness will completely block both electric and magnetic fields.

>>>
>>> This is part and parcel to the world of isolated and shielded
>>> circuits. The electrostatic shields are as effective as they are
>>> complete in their coverage. Their contribution is measured in mutual

>>> capacitance between the two points being isolated. With a drain wire
>>> to ground, and a low enough Z in that wire, then that mutual
>>> capacitance tends towards zero (however, near zero is a matter of
>>> degree as I've offered in past discussion).
>>>
>>> Figure 5.28(a) shielding is quite common in medical circuit design,
>>> and mutual capacitance does equal zero; and yet signals and power pass
>>> in and out through magnetic coupling. Isolated relays are a very
>>> compelling example of magnetic transparency in the face of total
>>> electric shielding.

The mutual capacitance at DC equals zero. Time-varying electric fields
penetrate the shield if it's thin in terms of skin depth.

>>> Magnetic shielding operates through reflection or dissipation
>>> (absorption loss due to eddy currents). This loss is a function of
>>> permeability ï¿½. Unfortunately, permeability declines with increasing
>>> frequency, and with declining field strength. Basically, all metals
>>> exhibit the same characteristic ï¿½ above VLF; hence any appeal to
>>> "magnetic materials" used to build antennas is specious.

This is not true. Metals do indeed exhibit varying permeabilities at RF
and above. This can be illustrated by a number of means, a common one
being the efficacy of a powdered iron core.

Electric field shielding also operates through reflection and
dissipation. Permeability affects both, because of its effect on
material wave impedance and skin depth.

>>> This is not to say the magnetic shield is ineffective, merely derated
>>> seriously from what might be gleaned through poor inference by reading
>>> ï¿½ values from tables.

Permeability does indeed change with frequency for a variety of reasons.
Consequently, some intelligence (and often measurement or guesswork) has
to be used to determine what it will be at the frequency in question.

>>> However, it is quite obvious that transformer inter stage shielding
>>> and the faraday shield found in AM transmitters is not seeking to
>>> optimize this attenuation, far from it. Thus the degree in isolation
>>> is found in the ratio of the mutual capacitance between the two points
>>> before and after shielding; and the attenuation in magnetic flux
>>> induction introduced between the two circuits after shielding.
>>>
>>> Returning to Ramo, et. al, the introduction of a partial shield.
>>> Figure 5.28(c) is effective insofar as its ability to reduce mutual
>>> capacitance.

Indeed it is. This is not, however, an example of a (time-varying)
magnetic or electric field existing in isolation.

I readily agree that a static electric or magnetic field can exist in
isolation from the other, as I'm sure all other participants to this

discussion do. But not time-varying ones. You can greatly change the E/H ratio, but you can't make it zero or infinite. And whatever you do will have only a local effect -- the ratio will rapidly approach the intrinsic Z of the medium as you move away from the anomaly which modified the ratio. Rapidly, that is, in terms of wavelength -- it can be quite a physical distance at very low frequencies.

If I have to look at the keyboard I'm in trouble. My fingers know
where the keys are, but I don't. <:-)) If I'm on the telephone and
taking notes it'd be faster to use a pencil. OTOH I can at least read
my typing.

I was net control for a weather watch net with tornado warnings out
all around us (Lower Michigan). When I did the summary after the net I
realized I need a head set with VOX built in so I can have both hands
free.

When I was a kid I bought a typing book, borrowed an old mechanical
type writer and taught myself. It really didn't take all that long.
I'd guess It took about the same time to get to 60 WPM on a mill as it
did 20 on a key.

My wife remarked that having worked in clerical and administration for
the state she knew a number of people who could type 100 WPM. I asked
if that was mistake free as corrections take time. It turned out they
were considerably slower when mistakes were taken into account. OTOH
when I was a sysadmin for a large corporation one of the system admins
could type so fast the keyboard buzzed. You could watch the
characters flow across the screen and in both directions. If he made

a mistake it might take him two words to recognize it, go back and
retype. I think he still was making over 100 WPM.

My wife and son can both type, error free at about that rate. I took
a typing course in the summer when I was in high school and passed the
10wpm error free test. I think in my case it was 10wpm and at least one
word error free :-)

My first wife's sister was able to type faster than an IBM selectric typewriter
(165wpm) error free. She won awards and contests for it.

>transmission line as a conceptual training aid for the
>uninitiated.

I gathered that from an earlier post, but I think the confusion comes
in the second second, doesn't it? 100 watts of power is generated
from the generator for two seconds. the first second, 100 watts
travels to the antenna and only 100 watts is in the transmission line.
Then for the second second, 100 forward watts is moving towards the
antenna and 50 reflected watts are returning to the transmitter for a
total of 150 watts in the transmission line? Of course, since the
transmitter isn't matched to the antenna, the reflected power is
reflected again for 25 watts being reflected back to the antenna
bringing the power from 100 forward watts to 125 watts (the reason
power meters go up in wattage when SWR rises) thus the antenna
reflects 62.5 watts which adds to the 125 for a total of 187.5 watts
in the transmission line. Sooner or later one will have a meltdown
that will make Chernoble look like a firecracker compared to a
fireworks display. lol

is that line 1 second long, or 1/2 second long?? a 1 second long line would take 2 seconds worth of energy from the generator before the reflection returned to let it know the line is terminated. this is of course very important if you are measuring lines with tdr's where you can really see those returned waves, of course the time it takes them to get back to the tdr is double the one-way travel time... mess it up and you are looking for faults twice as far down the line as you calculate.

Actually, the forward power levels off at 200 watts during steady-state. The reflected power levels off at 100 watts. 300 joules of energy exist that have been sourced but not dissipated in the load. 300 joules are exactly what the forward wave and reflected wave need to support their existence.

Here's the brainteaser configuration:

100W-SGAT---one second long lossless 50 ohm feedline---291.42 ohm load

The 'SGAT' is a signal generator equipped with a super fast auto-tuner that re-reflects all the reflected power back toward the load so there are no losses at the source end. The only losses in the entire system are in the 291.42 ohm load which, to make the math easier, was chosen for a power reflection coefficient of 0.5, i.e. half the incident power is reflected at the load.

I will generate an EXCEL spreadsheet today that will give a second by second summary of the powers and total energy.

In the meantime, here is a more simplified version of the brainteaser.

100W-SGCL---one second long lossless 50 ohm feedline---291.42 ohm load

The 'SGCL' is a signal generator equipped with a circulator and 50 ohm resistor. During steady-state, half the generated power is dissipated in the load and half in the circulator resistor. There are no re-reflections at the source.

During the 1st second, the source supplies 100 joules into the feedline. There is no dissipation either in the load or circulator resistor.

During the 2nd second, the source supplies another 100 joules into the feedline, 50 joules of which are converted to heat in the load and 50 joules of which are reflected from the load as 50 watts of reflected power. At the end of the 2nd second, the feedline contains 150 joules of energy.

During the 3rd second, steady-state is reached. Of the 100 watts sourced, 50 watts are dissipated in the load and 50 watts are dissipated in the circulator resistor. At the end of the 3rd second, the source has generated 300 joules, 100 of which have made it to the load, and 50 of which have made it to the circulator resistor.

300-100-50 = 150 joules stored in the feedline.

100 joules are stored in the 100W forward wave. 100 joules/sec = 100W

50 joules are stored in the 50W reflected wave. 50 joules/sec = 50W

This conservation of energy works for any length feedline. If the feedline were one microsecond long instead of one second long, there would be 150 microjoules stored in the feedline, 100 microjoules in the forward wave and 50 microjoules in the reflected wave.

The line is 1 second long. The source is generating 100 watts. So the
number of joules generated starting at t=0 is 100N where N is the
total number of seconds. At the end of 30 seconds, the generator will
have sourced 3000 joules which must be conserved.

I will generate an EXCEL spreadsheet at work today and post it to
my web page when I get home. It will cover the first 30 seconds
in 1 second increments. It will show that of the 3000 joules sourced
by the generator during that first 30 seconds, only 2700 joules have
reached the load. The other 300 joules are contained in the 200W
forward wave and 100W reflected wave.

(200 watts)(one second) = 200 joules in the forward wave

(100 watts)(one second) = 100 joules in the reflected wave

200 joules + 100 joules = 300 joules not delivered to the load

I have a wire dipole and an inverted Vee each cut to resonance on a
desired frequency. I would like to add a reflector and/or a director
(one at the time) to make each one a beam. Will adding the reflector
and/or director change the resonant frequency, or just the impedance?

Thanks
Buck

Hi Buck

Isnt Resonance defined as the frequency where the Impedance has *no*
reactance? Wouldnt that imply that the resonant frequency of the antenna
will always change if its impedance changes?
Can you *ever* change one without changing the other?

This is not aimed at people who don't care about such things.
This is aimed at people who do care about such things especially
those who are disseminating false technical information about
such things.

Some say that since there's 100 watts in and 100 watts out
during steady-state, there's nothing left over for the reflected
waves. They apparently forgot about the time immediately
following power up when there was 100 watts in and less
than 100 watts out.

You're absolutely right Cecil.

There is no reason for anyone, including me, to personally attack
others or to rant and rave like a lunatic.

It absolutely ruins techincal forums when people get too personal, no
matter who does it. I think that is a major reason why this newsgroup
fell from being very popular to barely used.

Hello Gary,

Although I'm not advocating "radials" or any other marine HF grounding approach, I am trying to understand the reasoning used by those who do advocate. I've tried to set up instrumentation that would allow comparative measurements of alternative "ground" properties for yachts, but the problems involved have been overwhelming. I think I understand why the world is not awash in empirical data in this area, especially compared to what is available for land-based verticals.

> First, radials on a boat are not usually better than a good ground to
> seawater.

I think the word "radials" in this thread ought to be in quotes, since we're really not talking about conventional symmetrical radials from

which radiation is substantially canceled. As you point out, the "radials" being discussed in this thread are simply a horizontal part of the radiating antenna and not really radials at all.

Having said that, I would welcome learning your basis for the conclusion, and any info you can offer on how much better and in what way. Do you have a measurement of the HF "ground resistance" provided by seawater using a Dynaplate? Would your conclusion change for a vessel on the Chesapeake where salinity is quite low?

> and control cables radiators as well, because of the higher impedance
> of the radials.

We don't seem to require that the backstay (or whatever vertical radiator we are using) be a physical 1/4 wavelength when we use a tuner. Why would we impose that requirement on the horizontal part of the radiating system? Isn't the famous 100 square feet of copper approach analytically equivalent to a nonresonant "radial"?

It is true that proximity of the horizontal radiator to other wiring can cause problems, and this may be an unequivocal disadvantage to the approach. Of course, an entire sailboat is in the reactive near-field region of the vertical radiating element regardless of the "ground" used and so the coupling issue is a matter of degree.

>

> it to go but a large part of it will get into all sorts of things on
> the boat that you don't want it to.

There are two issues here: interference (already discussed above) and efficiency. Assuming no communication value is given to near-vertical radiation angles (a mistake, in my opinion, for the lower frequencies), the efficiency of an L-shaped, center-fed radiator is probably no worse than 3 dB below that of the same vertical element worked against a perfect ground plane. That is based on simply assuming that 100% of the power that would have been radiated by the horizontal element is dissipated in the "ground". In practice, the typical Dynaplate-based ground plane will be less than perfect, even over salt water, and the

horizontal element will most definitely radiate some power. Hence, my suggestion than 3 dB is worst case and I would not be shocked to see the Dynaplate-based system less efficient. Data, data, data.

>
> Radials on a boat are different than when laid over earth. When laid
> over earth there is tight coupling to the earth and length is not
> important.

If we're now talking about real radials, I wonder if the statement is true. Real radials elevated three feet above seawater might couple very tightly. It would be interesting to see some analysis or measurements of this. But we're talking about "radials" in this thread and the statement is not relevant to them.

When they are elevated above earth they need to be resonant
> in order to work. Short radials do little good in this situation.
> A boat installation is similar to an elevated installation on land.

As mentioned above, I believe elevated radials (real radials) need to be resonant and symmetrical in order to cancel radiation from them. The problem is semantic, of course. A radiating structure with horizontal and vertical components can be 100% efficient with the horizontal components nowhere near resonant lengths. There will be effects on horizontal and vertical patterns but that is impossible to generalize.

>
> I see some guys on the Maritime mis-information forum spouting about
> using radials on a boat.
>
> You are much better off getting a connection to the sea for your
> ground. It is one of the best ground planes available.

I'm curious about how these ground plates work. The attenuation in seawater of RF at 10 MHz is on the order of 30 dB/foot. If a ground plate is four feet below the surface, how does it work? Copper's conductivity is orders of magnitude better than seawater. Do we know the break even point for a copper wire ground plane vs. seawater? Reflection properties of seawater OTOH are well-known and documented.

http://ecjones.org/physics.html
Ionospheric Physics of Radio Wave Propagation

The usual instructions for installing ground plates recommend bonding the RF ground connection to metal tanks, the engine, lifelines, the mast and associated steel rigging (other than the insulated backstay) etc. Sometimes I wonder if all that metal is not forming the "other half of the dipole", pretty much independently of the ground plate's existence. Since a good many installations disregard your recommendation to mount the tuner close to the ground plate, rather than close to the antenna, that 10 feet or so may contribute to the "size" of the counterpoise when a ground plate is used.

I suppose this is heresy, but disproving it would require testing a ground plate with NO connections to the tuner other than transmitter, antenna and ground plate. A manual tuner would make sense for the test. Of course the transmitter would have to be run from an isolated battery so as not to bond the tuner to the boat's DC ground wiring. To make sense of the feedpoint impedance, the antenna should be a quarter wavelength to provide a known radiation resistance, but much of it would be buried in the hull, etc. It quickly becomes complex.

Another factor is that at the higher frequencies, a typical backstay approaches or exceeds a half-wavelength, in which case even a "short" length of wire, with or without a ground plate, will work well. If the ground plate is providing one of the best ground planes available, its impedance should actually decrease with decreases in frequency, given the attenuation of seawater as a function of frequency. Thus, the ground plate should be spectacular at 160 meters. Alas, I have not seen even anecdotal information on that.

To do so you
> need a very short ground lead from the tuner to the sea connection.
> The best way to accomplish that is to mount the tuner down in the hull
> right next to the sea ground connection within a foot or so. Then run
> your antenna lead from the tuner to the antenna as much in the clear

> ground connection to the sea water connection that 10 feet will
> radiate like the antenna. Problem is so will the coax and tuner
> control lines radiate and couple into all sorts of places you don't
> want it to.
>

Without some kind of isolation, that is true. The flip side, though, is that (as you pointed out) the antenna starts 10 feet "lower" and a good deal of radiation from that 10 foot length is now inside the hull. If your objection to the use of "radials" is unwanted coupling, then this must surely fall into the same potential (no pun) category.

> By placing the tuner at the ground connection you have control over

You're correct about the definition of resonance.

Buck's statement would have made more sense if it the last words were
"just the resistance", and that's likely what he meant.

Sure, you can change the impedance without changing the resonant
frequency -- a transformer will do that, for example. At resonance, the
resistance will simply be a different value.

But to answer Buck's question, adding another element will almost
certainly change both the resistance and reactance at the feedpoint, and
therefore the resonant frequency.

Hi Roy

I'm not qualified to enter into a theory discussion with you. But, I'd expect the introduction of a nearly half wave long comductor into the near vicinity of an antenna that has a purely resistive Terminal Impedance (Resonant) will change the Terminal Impedance of the new antenna which is the combination of the two.
I would have considered that transformer doesnt actually change the antenna's Terminal Impedance (Resonance) the transformer converts the antenna's impedance *at a new location*.
So, I'd expect the antenna's "resonance" to be defined by its "impedance".

I've considered that any R+/-jX can be Transformed to an impedance thats purely resistive. But, with antennas, thats a matching situation, while the antenna's terminal impedance remains reactive.

What is the reason that Rohn uses two differant size bolts on the legs of the 25G tower ?

I am sure there is a good one or they would not have done that.

Both most likely.

Download the demo eznec and model it; www.eznec.com.

After you've used it a few times, you'll want to buy the full version.

Nope, no connection with eznec. It has saved me a lot of time, effort,
and cut up wire though.

I've lost the original question.

But there is a lossless transmission line 1 second long.
With a velocity factor of 1.0 it is 30,000 kilometres long.

Let Zo = 100 ohms.
Let applied volts = 100 VDC.
Let terminating resistance be 100 ohms.

Line Inductance = 10,000 Henrys.
Line Capacitance = 1 Farad.

Under steady state conditions -
Line current = 1 amp.
Energy stored in inductance = Sqr(I)*L/2 = 5000 Joules.

Volts across capacitance = 100 volts.
Energy stored in capacitance = SqrV)*C/2 = 5000 Joules.

Total energy stored = 10, 000 Joules = 10,000 watt.seconds.

Which has nothing whatsoever to do with all this nonsense about
reflections. Note that energy in inductance equals energy in
capacitance.

(I trust I have not made a mistake with the arithmetic.)

Reg.

Sorry, once again I miss your point. I maintain that time-varying electric and magnetic fields cannot exist independently, while you claim that they can. Tom and I asked for an example of a case where they do, and your response did not contain such an example.

Yep, you don't have to mess with those pesky reflections when the line is terminated in a load equal to its characteristic impedance. Then the problem reduces to the trivial one you've posed. Simple problem, simple solution.

good question, i've always thought it was to be sure the sections were fully mated... you couldn't put in the big bolts unless those holes lined up which prevented bolting up a partially mated joint.

What you need to understand is just what kind of antenna are you trying
to describe, here as a MF/HF Marine Antenna? Are you thinking a Marconi,
Vertical Dipole, Offcenter Feed Marconi, or just what? The standard
MF/HF Marine Antenna, usually is considered a Marconi, and that is what
MOST both commercial and non-commercial MF/HF Marine antennas end up
being. So lets discuss Marine Marconi Antennas, and what makes good
ones and bad ones. Marconi Antennas are charactorized by 1/4 Lambda
Vertical Radiating Element, sitting in close proximity to a LOW
Impedance RF Ground System Perpendicular to the 1/4wave Vertical.
In the MF/HF Marine enviorment we add a Tuner, Auto or Manual so as
to be able to tune the Vertical to a 1/4 Wave Electrical Length and
Resonance on each frequency that the vessel maybe required to use in the
MF/HF Marine Frequency Bands, which cover 1.6Mhz to 25 Mhz in frequency.

Ok now lets look at what the vertical is. A Backstay, a Whip, a Loaded
Whip, a Loaded Whip with wire under it. It really doesn't matter, as
they all will be tuned to resonance, in either 1/4Wave, or 3/4Wave by
the tuner, against the impedance of whatever RF Ground is connected to
the tuner.

Hence the "Old RadioMans Addage", "If you have a Good RF Ground,
anything will radiate a good signal, even a wet noodle, but even the

best antenna will radiate poorly if it is working against a poor RF
Ground."

It is the RF Ground, that determines how WELL Marconi Antennas work.
Always has, and always will.
>
> Having said that, I would welcome learning your basis for the
> conclusion, and any info you can offer on how much better and in what
> way. Do you have a measurement of the HF "ground resistance" provided by
> seawater using a Dynaplate? Would your conclusion change for a vessel on
> the Chesapeake where salinity is quite low?

Ok, lets look at what RF Ground really means in MF/HF Marine Antenna
Systems. Put on your "Bruce's Special RF Glasses" and look at you
vessel, and lets see what the Marine enviorment really looks like to
RF. Lets take a look at the wood or plastic hulled vessel over there,
what DO WE SEE? Well, we see the vertical radiator, we see the salt
water, we see the metal on the boat that is grounded electrically
together, (bonded) we see the engine if it has one, we see the piping
and wiring that is all connected electrically, or bonded to the engine,
and nothing else. Now remember that for a Marconi Antenna, IT IS THE
RF GROUND that determines the efficency of the system. What makes a
good low impedance RF Gound? Large Flat area, perpendicular to the
Radiator, very electrically conductive. Sounds just like Salt Water,
doesn't it. Hmmmm, wonder why most really good systems use the WATER
as the RF Ground? Dahhhh. Again, remember that we are looking for a LOW
Impendance RF Ground that doesn't have much of a reactive component to
it, so that it will be good just about anywhere in the 1.6- 25Mhz range.

> analytically equivalent to a nonresonant "radial"?
>
Ok, now lets look at what we have to use to build a good LOW Impedance RF
Ground with what we see using "Bruce's Special RF Glasses". One thing to
think about, Do we really want to make a direct connection to the WATER,
for our RF Ground, and if so do we want to make that Direst Connection
a DC CONNECTION? This question is where "Elctrolysis" comes into play,
and is beyound the scope of this lecture, so for convience lets assume

we want NO DC Path to the WATER. So how do we then couple the RF to the water effectivly? Well, we use a Capacator, and a capacitor is made up of "Two Plates seperated by an insulator. Our capacitor has one plate as the Salt Water, and the insulator is the Wood or Plastic Hull, and the other plate we need to build out of what we have aboard that we can see with our "Special Glasses". Now what are the factors that increase the capacative coupling in a capacator? Plate surface area, and plate speration, so we want as much surface area as we can get, as close to the Salt Water, as we can get. The higher the coupling, the lower the impedance of the RF Gound System, and the BETTER the antenna system wiull function.

> It is true that proximity of the horizontal radiator to other wiring can
> cause problems, and this may be an unequivocal disadvantage to the
> approach. Of course, an entire sailboat is in the reactive near-field
> region of the vertical radiating element regardless of the "ground" used
> and so the coupling issue is a matter of degree.
>

Not a real big issue here. Near field is basically unimportant in Marconi Antenna Systems, except for Near Field Grounded Verticals within a few feet of the Vertical Antenna.

>
> Chuck
> NT3G

End of Lecture Part 1 MF/HF Marine Radio Antenna System Design / Simplified

It's the Ground, dummy, the RF Ground........

Bruce in alaska an Old MF/HF Marine RadioMan from way back.....

As I say, I've lost the original question.

But if a steady-state answer is needed for the original question then the answer can be found by the same simple means without the unnecessary complication of reflections.

It's the Devil which makes Cecil pose such loaded questions.

Reg.

Sigh. Yes, I believe you HAVE made a mistake in your calculations,
right at the beginning. C = tau/Z0 = 1/100 farad; L = tau*Z0 = 100
henries. But of course, the concept is perfect. 100V, 1A, 100W,
E^2*C/2 = 50 joules stored in the capacitance. I^2*L/2 = 50 joules
stored in the inductance. The two are equal only for a termination
equal to the line Z0 of course.

Too bad Cec doesn't understand that lossless line has unvarying Z0 as a
function of frequency from DC up, as long as TEM mode is supported.

Cheers,
Tom

> It's the Devil which makes Cecil pose such loaded questions.

It's only loaded with the conservation of energy
principle, Reg. Here's a simple example. The SG-CR
is a 50 ohm signal generator equipped with a
circulator resistor to dissipate all reflected
power incident upon the source.

200W SG-CR---one second long lossless 50 ohm line---291.42 ohm

SWR is 5.83:1 rho^2 = 0.5 Steady-state forward power
is 200 watts. Steady-state reflected power is 100 watts.

The question is: After steady-state has been reached, how
many joules of energy have been generated but have not been
dissipated in the load resistor or circulator resistor?

I do understand that. That's why Reg's 10,000 joules don't make
any sense to me. Now if the Z0 was one ohm at DC, it would make
sense for 100 volts to be able to supply 10,000 joules in one
second.

Reg Edwards wrote:
> I've lost the original question.
...

Actually, it was "200 watts forward, 100 watts reflected" -- but it works the same way: 100 ohm line, 1 second long: source is DC 200*sqrt(2) volts in series with 100 ohms. Load is such that it absorbs 100 watts from that source: 100*(3 +/- sqrt(8)) ohms. About 17.16 ohms works OK. Then the line voltage is 41.42V and the energy stored in the 1/100F line capacitance is 8.579 joules, and the line current is 2.414A and the energy stored in the 100H line inductance is 291.421 joules. Total energy stored is 300 joules.

It's somewhat comforting that it's just as you'd expect from power delivered versus time. It's an illustration of something I believe Ian White was trying to get across in another thread: there are commonly multiple ways to analyze a problem, and if they agree, you MAY have the right answer. If they disagree, you have at least as many wrong answers as the number of disagreements (or perhaps the disagreements only seem to be disagreements).

Now, I have no idea who it is that might be saying that there's no energy stored in the fields in a line, so I really don't know what the to-do is all about. Maybe it's just another misinterpretation of what people have actually said...perhaps about lines that are very far indeed from being lossless.

Cheers,
Tom

Tom,

Furthermore, the energy dissipated each second in the 100-ohm
termination (100 watts) is equal to the energy stored in the line.

Damned decimal points. I just KNEW I had made a mistake somewhere
along the line. Thank you.

By the way - what is tau ?

Reg.

As can be seen from http://www.qsl.net/w5dxp/1secsgcr.gif

Do you think it's just a coincidence that 200 watts of forward
power in a one second long line would require 200 joules and
100 watts of reflected power in a one second long line would
require 100 joules for a total of 300 joules?

> Now, I have no idea who it is that might be saying that there's no
> energy stored in the fields in a line, so I really don't know what the
> to-do is all about.

Please read what W7EL says about forward and reflected power
in his "food for thought" writings. In particular: "Some inventive
people have supposed they can separate forward and reverse power with
a circulator. That really sounds attractive, particularly with an open
or short circuited load. In that condition, the forward and reverse
powers are each 100 watts, yet the transmitter (or the transmitter
voltage source) doesn't have to produce any power at all."

What W7EL doesn't seem to realize is that the source produced the
power in the forward and reverse power waves while the feedline
was charging up during the transient period before the reverse power
waves reached the source so there is bona fide energy in those waves.
He also says there is no model for handling such yet one exists in
detail in the magazine article on my web page.

Source record: 58802

I am using screw-on antennas on my Ramsey DF rig.

The threaded (female) barrels keep coming loose in the antenna tube --
where they appear to be locked by a groove and four tiny punches in
the tube.

I have tried solder, but it does not adhere.

Any other suggestions?

Ken KC2JDY

Antenna resonance is defined by its element's electrical properties,
"caused" by its physical properties/dimensions.
In case of 3 el "conversion" from Inv Vee, you have to picture elements as a
tuned circuits. If they are spaced within a fractions of a wavelength, they
have mutual impedance, affecting each other. As you start adding elements,
they add capacitance to the system and lower the overall resonant frequency
and impedance. Single Dipole is around 75 ohms, 3 el. Yagi around 30 ohms.
The more elements you add, the more sensitive the design is and requires
more prunning for optimum performance. So just slapping elements to Inv Vee
dipole will not produce optimized antenna. EZNEC, 4NEC2, MMANA are an
excellent tools to demonstrate that and to optimize the design, give you
dimensions and impedance and understanding behavior of antennas, give
current distribution in elements, plots of impedance, gain and other
parameters.

Yes, the "offending" transmitter needs to be in close proximity so that

1- the offending junction(s) are sufficiently illuminated by it to produce
strong enough sidebands to be a problem in the offended receiver.
2- The offended receiver has to be close enough to be offended by the levels
involved.
>
> The Navy, for whom I work, bonds (or isolates) everything ...
> Every spark, no matter how small, is an RF generator.

It isn't necessarily a spark, in fact probably infrequently sparks unless
you're dealing with higher power. It goes like this.

Both sides of the offending junction are picking up RF. They are
conductors, so there are RF currents flowing. When there are RF currents
flowing you have radiation. As the junction opens and closes, the RF
currents change. When the junction is making contact, current can flow -
when disconnected, current can not flow (pretty much; let's not get into the
capacitance thing). The changes in current with a noisy contact will mimic
the "noise" of that contact. The radiation will therefore mimic that noise
also. That noisy radiation will sum with the original, desired radiation.

This, in effect, modulates the radiated signal after it leaves the transmitter. If it is sufficiently high level and the receiver able to pick it up, you have a problem..

Chains
> are awful. We hate chains.

Perhaps you know, but during the Apollo space shots, there were NASA ship at sea which had really high power HF transmitters. They would interfere with the radars. It turned out that the deck chains were the offenders. Whether or not there were sparks, it shows just how wide band the noise can be.

Gee... What's the resonant frequency for a deck chain link?

"Improvement" implies a change; but I have always held the same view as quoted above.

It is one of the main reasons why I remain sceptical about your theories. Where they ought to be agreeing with other analyses of the same problem, they don't.

Also, "gobbledygook" is not a word I use... it's one of yours, I believe.

The Armenian judges gave this a 9.8 on the Olympic Troll-O-Meter,
but they were overruled by the umpires in instant replay, who
awarded it a 2.6.

The Armenian judges lodged a formal protest!

It was sufficiently trollish, of course, but way too obvious.
It was poorly written, poorly executed, and was so incredibly
lame as to lack the true drawing power of a really masterful
troll. Maybe as high as a 3.1 for the intense stupidity of the
premise, but a 9.8? Never! The Armenian judges tear their
hair out, throw their balalaikas down in dismay, and perform
the traditional Armenian Dismay Chant! They demand a recount!

I put this aside until I could do a little modeling. A lot of postings have been made in the interim, but I don't see too much in the way of answers. I'll try to answer some of your questions.

Will wrote:
> I want to set up a hf antenna for my sailboat.
>
> I have read various guides from Icom etc.
>
> They suggest running copper foil to a Dynaplate and use sea water as
> the ground. How can this work when the Dynaplate is below sea water?

I don't know anything about Dynaplates, but if it's on the hull, it's very near the surface of the water. Any current it conducts will flow along the top of the water displaced by the hull. If, on the other hand, it's really under any depth of water at all, it'll be invisible to RF and might as well not be there.

> Is sea water equal to copper wire radials as a RF ground system?

Yes.

> Does sea water make a good enough ground without radials?

Yes. A foot-long wire "ground rod" below the antenna provides a nearly lossless ground connection at HF.

> How can a piece of copper metal about 1 ft square equal several
> radials laying on the boats deck?

Radial wires are used for land based systems because of the poor conductivity of soil. Radial wires reduce the resistance of the path current takes going to and from the antenna base. Salt water is a good conductor and doesn't need -- and won't benefit from -- radial wires.

> Why do i have to use copper foil when most other people suggest using
> ordinary copper wire?

You don't. And won't copper corrode rapidly in salt water?

> Over seawater what would be the best number of radials to use
> considering that maximum length i can run is 40 ft. I am planning to use
> a backstay antenna with a SGC 230 Tuner.

None. A simple wire down into the water is adequate. Or use a small plate very near the surface if you prefer.

>
> 1. What is the skin depth in salt water at 14 MHz?

About 2.4 inches.

How would this affect
> a ground plate at four feet below the surface?

A ground plate at that depth would be invisible to RF. It might as well not be there. This is, of course, assuming it actually has 4 feet of water above it and not a boat's hull and air.

> 2. What would the ohmic losses be over a one square foot by 33 foot path
> through salt water?

Let's see, salt water conductivity is about 5 S/m, which is 1.524 S/ft. So the *DC* resistance of that piece of sea water would be 1.524 * 33 / (1 * 1) ~ 50 ohms. But the RF resistivity would be much greater because only the outer few inches would carry any current.

> 3. How well would the ground plate work on fresh water bodies, such as
> much of the Chesapeake, the Great Lakes, and various rivers and
> tributaries often used by cruisers? How would it compare with radials
> over fresh water?

Fresh water is quite a different story. The skin depth in *pure* fresh water at 14 MHz is 156 feet. But "fresh water" is far from pure. Unfortunately I don't have any ready data on "typical" "fresh water". So the skin depth is somewhere between 2.4 inches and 156 feet. Not much help. If the water is pretty pure, radials near the surface would be an improvement over a ground plate.

> 4. Can anyone cite a published and reproducible study in which the RF
> losses through salt water were measured and compared with losses through
> one or more copper wire "radials" on or below deck of a typical cruising
> vessel? Or is there a published theoretical analysis of this comparison?
> Looking for more than the casual, anecdotal stuff.

No. An NEC-4 model shows a one-foot wire to provide a nearly perfect ground in salt water. But that falls far short of your requirement.

> 5. Will a four foot length of wire dropped into saltwater provide a
> "good" RF "ground" and on what is the answer based?

Yes, but one foot does just as well -- any current on the wire will drop
to essentially zero within the first foot, so the remainder might as
well not be there. This is from an NEC-4 model.

We never actually get to what it is that is disagreeable do we? This
is merely the window dressing for backing into an oblique translation:

>Am I mistaken, then?

Who can tell but you? It is, after all, your statement that you
disagree. We can only guess.

>Were you agreeing all along that a time-varying
>electric or magnetic field can't exist independently and therefore there
>can't be completely inductive (H field) or capacitive (E field) coupling?
A 30 word speech dressed as a question is not clear writting. :-)

Agreeing all along?
No, I am never in the habit of agreeing all along.

A time-varying electric or magnetic field can't exist
independently?
Fields in free space are intimately joined and inseparable.

There can't be completely inductive (H field) or capacitive (E
field) coupling?
If I am not mistaken, this is the same question again. Do you in fact
see any difference between the two that merits the boolean AND?

Should I anticipate other philosophical questions such as
Are you agreeing all along about conductivity and Ohm's law?
Let me shock you and say NO so as to not deflate others' anticipation.
I bet they will know how to pin me down. ;-)

Hi Yuri

I thought my statement that an antenna's Resonance is defined by that
antenna having an impedance thats purely resistive, was an accurate
statement. Is than *not* accurate?? What other "electrical properties"
define an antenna's resonance??

> Gee... What's the resonant frequency for a deck chain link?

UHF or SHF, but it doesn't much matter. The training aids for the EMI
Awareness course I used to teach at San Diego Naval Station (command =
FTSCPAC, if you know that outfit) included a funky little plywood ship,
within which were two milliwatt-level HF "transmitters" and a receiver.

I/we demonstrated with two links of chain, connected back-to back to make a
continuous current path, that we could generate noise by making and breaking
the connection where the links touched. It was invariably a convincing demo
for the students. The effect only extended out a few inches from the deck
of our plywood model, but scale it up, and you are smack-dab in the real
world.

Maybe I used the wrong word, 'resonance', but I was referring to the
lowest SWR match, which I would assume for the example to be less than
1.5:1 on a given frequency.

To be more specific, assume a 20 meter inverted vee trimmed to minimum
SWR at 14.225. Would adding the reflector, and then the director
(assuming I match the coax tot he antenna impedance) raise or lower
the tuned frequency of the antenna?

Source record: 58682

In a previous posting, I noted that for the 100 ohm line driven by 200*sqrt(2) volts DC through 100 ohms, there are two load resistors that dissipate 100 watts: 100*(3 +/- sqrt(8)) ohms. Continuing the observation about energy stored in electric versus energy stored in magnetic fields, for the low resistance, the steady state load and line voltage is low and the current is high; for the high resistance, the steady state voltage is high and the current is low. In the first case, 8.5786 joules is stored in the electric field and 291.42 in the magnetic; in the second those are reversed and 291.42 are stored in the electric and 8.5786 in the magnetic. The ratio of the two energies is exactly the same as the ratio of the load resistances.

In our lossless line, if the excitation is AC and steady-state has been reached, then the total energy stored per unit length varies as a function of time and distance in a somewhat complex manner. The ratio of electric to magnetic varies along the length of the line and as a function of time, with extremes being in a ratio equal to the square of the SWR, occuring of course at voltage and current maxima, spaced 1/4 wave apart, alternating down the line.

I'm not sure that those observations will be any use to anyone, but maybe they are of academic interest. Who knows what I might come up with after some Glenmorangie.

Cheers,
Tom

Lowest SWR is not the same thing as resonance.

This is one of those cases where the Smith chart is a good visual aid [1]. Here's a three-step guide:

1. The Smith chart is just another kind of "map projection". Instead of plotting latitude and longitude, we are plotting the resistive and reactive parts of complex impedances.

Geographical map projections are chosen to make certain features easy to see correctly, eg distance, direction, or area. The peculiar shape of the Smith chart is also designed to make certain things easy... once you've learned how to read the map.

2. All purely resistive impedances are on the "meridian line", the symmetry axis passing through the center of the chart. The resistance scale is nonlinear so that resistances from almost zero to almost infinity can be plotted. Impedances that lie anywhere off that meridian line have a reactive component. Anywhere inside one half-circle is inductive; anywhere in the opposite half-circle is capacitive.

3. At the center of the chart is your chosen system reference impedance (usually 50 ohms resistive). When you plot an impedance anywhere on the chart, the distance from the center point indicates its SWR, and the direction indicates the phase angle [2]. This gives the Smith chart one of its special features: you can draw circles of constant SWR.

It would obviously have been much easier to say that with the help of a drawing [3] but hose three points are all you need to know in order to use the Smith chart as a visual aid.

In particular, it is enough to *show* you the difference between resonance and lowest SWR.

When you plot the R-X impedance of your antenna against frequency across an amateur band, it traces a short arc on the Smith chart. If the antenna is supposed to give "a good 50-ohm match", the whole arc has to stay close to the center of the chart.

The frequency of minimum SWR is where the impedance arc passes closest to the exact center of the chart. The resonant frequency is where the arc crosses the meridian line (zero reactance). Those two frequencies are generally not the same.

[1] Reg will disagree; but Reg also has the kind of mind that can lift the same information straight out of the transmission-line equations. The Smith chart is for "the rest of us" who need to think in more visual terms. Fortunately those two different viewpoints are converging: we can now have computer programs that solve the equations exactly in the background, and plot them on the screen as a visual aid.

[2] Strictly speaking, radius is directly proportional to the magnitude of the reflection coefficient. One complete turn around the chart represents 180deg of phase angle, for the same reason that impedance along a (lossless) transmission line repeat themselves every HALF wavelength.

[3] The ARRL Antenna Handbook (current 20th edn) has a good chapter about understanding and using the Smith chart... with real drawings.

I think we all would be interested in how a small piece of metal buried
in sea water can provide an efficient ground versus one or 2 elevated
radials. I also dont see how its efficient concentrating all your
current in such a small area. Since the salinity of salt water is not
constant using one or 2 radials on yacht would be more efficient.

How can salt water which would have some resistance even though
its conductivity is high compared to earth behave better than copper
wire when returning antenna currents to the feedpoint. The small amount
of current flowing in a 100 watt signal i would not want to waste
sending it into salt water. Salt makes good resistors, why would you
introduce a loss into the equation which radials seem to eliminate
even though we dont have ground loss over sea water? We also have the
issue of the skin depth of sea water to consider.
>
> Yes. A foot-long wire "ground rod" below the antenna provides a nearly
lossless ground connection at HF.

This is not how most yachts connect their ground connections. They
connect to the sea cocks well below the top of the water anywhere for

3ft to 5 ft down. Some even use slim flat ground shoes again well below
the water line. Its impractical for a any sail vessel to maintain a
connection to sea water close to the surface because loading and the
yacht heeling when sailing.

Indeed radials do perform this way. I would still want to use radials
wires even 1 or radials wires even on a yacht since the length of the
radials will have a greater capacity to sea water ground. It also would
be more efficient in providing a current return.

plate very near the surface if you prefer.

Again yachts bury their ground connection well below the skin depth.
Some even run the ground wire from the tuner down to the keel which is
well submersed in salt water. All they are using is one short piece of
foil that is behaving like a small radial. We will see what the models say.

2 elevated radials over seawater versus a 1 ft square piece of metal
buried below the skin depth. My money would be on the radials.

'Resonance' means where the reactance is zero.
'Lowest SWR' usually means SWR read on a meter calibrated
for 50 ohms. These two conditions may be quite different.
40+j10 is not resonant but has a 50 ohm SWR of 1.4:1.
10+j0 is resonant but has a 50 ohm SWR of 5:1.

Wow, I sure generated a lot of complex discussion. This was supposed
to be a general question with a simple answer such as, "Yes, the
dipole or inverted vee will have to be lengthened." (or shortened).

I do gather from earlier posts that the driven element will shift
frequency with the introduction of parasitic elements.

Thanks for all the answers.

Hello,
I can not handle a problem which is about AGC. Please help me about
that. The conditions are;
It is required to design and implement an AGC circuit
with the following specifcations:
1. Amplitude of the input voltage may vary between 10 mVpp and 50 mVpp.

2. Amplitude of the output voltage should be in the range 0.9 Vpp
and1.1 V
pp for the input signals with amplitudes stated above.

3. Output impedance of the ampli¯er should be smaller than 2 k.

4. The circuit should be able to amplify the signals having frequencies
between 500 Hz and 10000 Hz.

The amplifer designed should be a single transistor amplifer in the
common-emitter form for BJT amplifers or common-source form for the
FET amplifers. However, it can be used extra transistors for making the
amplifer an adjustable gain amplifer.

And the AGC should be composed of 2 parts adjustable gain part and
feedback part.

Please help me urgently to design this problem. Thanks...

Please help me urgently to design this problem. Thanks...
==========
This sounds like a class assignment for an electronics design course.

> The circuit should be able to amplify the signals having frequencies
> between 500 Hz and 10000 Hz.

OK, its an "audio frequency" related amplifier design. Additional
requirement
that the single transistor amplifier be a common-emitter form for BJT
amplifiers
or common-source form for FET amplifier designs

> 3. Output impedance of the amplifier should be smaller than 2 k ohms&#65533;.

Speakers are 4, 8 or 16 ohm loads; 600 ohms is fairly standard in broadcast;
Original crystal set headphones (Trimm - vintage WW2) were 2000 ohms

> Amplitude of the output voltage should be in the range 0.9 Vpp and 1.1 Vpp
for the input voltage that may vary between 10 mVpp and 50 mVpp.

Standard amplifier with an AGC circuit - added requirements that the AGC should have
both an adjustable gain and feedback control.

Start with Google

Thank you for the detailed response, Roy.

A couple of issues still trouble me however.

If the skin depth at 14 MHz is about 2.4 inches, can we roughly assume that the RF resistance of that path is no less than 52.8 ohms (2.4*22 ohms)? This assumes most of the RF current would occur in the top one inch (attenuation at one inch would be about 15 dB), and that the resistance at 14 MHz is equal to the DC resistance.

A path one inch deep by 16 feet long (1/4 wavelength at 14 MHz) would then have no less than 26.4 ohms resistance at 14 MHz.

Now imagine a system of multiple one foot wide by 16 feet long copper radials on the ground with 26.4 ohm resistance distributed uniformly in each radial. Obviously such a system will be lossy, with an average radial resistance of 13.2 ohms.

While the analogy is a stretch, it illustrates the difficulty I am having in understanding how seawater can be considered more efficient than even a single slightly elevated radial, which is reported to be less than 1 dB worse than 120 quarter wavelength buried radials (ignoring slight pattern distortion). So even if seawater does constitute a less lossy ground plane than a single radial (yeah, apples and oranges, but we can weigh their juices I think) it would be better by less than 1 dB. .

Then there is the issue of the one foot long "grounding rod" immersed in the sea. If the above back-of-the-envelope analysis is valid, it would seem that a even one inch long rod would be more than sufficient. If we were dealing with a pool of liquid mercury or silver, this would have

considerable intuitive appeal for me. But the seawater model is troubling. I imagine seawater to be a lot like earth, except more homogeneous and with orders of magnitude higher conductivity. And I imagine a perfect ground plane to have conductivity orders of magnitude higher than seawater. I imagine even a modest system of copper radials to appear more like liquid mercury than seawater does.

Where am I going astray?

Imagine for a moment that instead of salt water that the ocean was covered by a thick metal plate. How would you effectively use that as a ground? Salt water isn't as good a conductor as metal, but it acts more like that than dirt.

I don't know how much the salinity or conductivity of sea water varies, but suspect that even at its worst it's quite a good conductor.

> How can salt water which would have some resistance even though
its
> conductivity is high compared to earth behave better than copper wire
> when returning antenna currents to the feedpoint.

Cross sectional area. Replacing all the sea water with copper would improve it, but scattering a bunch of copper radials out and replacing only tiny parts of it wouldn't make much difference. And the loss is so low to begin with that even replacing it with copper wouldn't make any difference.

> The small amount of
> current flowing in a 100 watt signal i would not want to waste sending

It won't go in very far. It'll stay very close to the top. And the waste is negligble.

> Salt makes good resistors, why would you introduce
> a loss into the equation which radials seem to eliminate even though we

Solid salt is actually a decent dielectric, I believe. Again, the trick is cross sectional area. The current is spread over a large area of water, so the overall loss is negligible.

The analysis I did took skin effect into consideration. The skin depth
is even less in metal, yet metal has low RF loss.

I'm sorry to hear that, because any connection below a few inches is
ineffective at HF.

More efficient than a deep plate, for sure. Not any more efficient than
a foot long uninsulated wire extending downward from the surface. But by
all means use whatever makes you feel well grounded.

If the wire is uninsulated, the first few inches of the wire will
provide the ground connection. If it's insulated, they'll have no HF
ground connection at all except what's provided by capacitive coupling
through the first few inches of insulation.

> All they are using is one short piece of
> foil that is behaving like a small radial. We will see what the models say.

By all means, do some modeling. The only program I know of which will
allow modeling submerged conductors is NEC-4 and derivatives.

> 2 elevated radials over seawater versus a 1 ft square piece of metal
> buried below the skin depth. My money would be on the radials.

Certainly elevated radials would be better than metal more than a skin
depth or two deep. Better yet is a wire extending from the surface to a
few skin depths. Why isn't that possible?

Incidentally, I'm not proposing replacing the standard grounding system,
which I'm sure is important for other uses including, probably,
lightning protection. It will just need to be supplemented if you want
an effective HF ground.

What you'd need to do is look at the I^2 * R loss for every little pie slice of water the current flows through. It's greatest near the antenna (assuming a vertical) where the current density is greatest. In that region, the current density is greatest and R is also greatest, so that's where the majority of loss occurs. (Which is why a radial wire field is useful for land installations -- its resistance is least near the antenna.) So you can't just calculate a single value of R or I based on the current and cross section at some point -- the entire area over which the current is flowing must be taken into account. The modeling program does just that.

Don't get too worried about the skin depth. Shallower skin depth is an indication of a better conductor. The skin depth in metal is extremely thin, yet it's a better conductor yet.

> A path one inch deep by 16 feet long (1/4 wavelength at 14 MHz) would
> then have no less than 26.4 ohms resistance at 14 MHz.

True but irrelevant. The current at the far end is much less than the current at the near end.

The problem is that the analogy is too much of a stretch. Too many incorrect assumptions were made, resulting in an invalid conclusion.

> Then there is the issue of the one foot long "grounding rod" immersed in

As it turns out, a one inch rod is nearly as good, even though it doesn't extend to the entire depth where significant current is flowing. Half the total current is below about 1.7 inches deep. To connect directly with essentially all the current requires at least several skin depths. Here's the relative current on a foot long wire directly below a quarter wave vertical at 14 MHz:

Depth (in.) I
0.5 0.81
1.5 0.53
2.5 0.35
3.5 0.23
4.5 0.15
5.5 0.10
6.5 0.07
. . .
10.5 0.01
11.5 0.006

At RF, taking skin depth into account, there's about 5 orders of magnitude difference between the conductivities of copper and average soil. Sea water is 30 times more conductive (at RF) than average soil, so it's still far short of copper. But Suppose we had a conductor which was 10 orders of magnitude more conductive than copper -- would it make any difference if our ground plane was made out of that or out of copper? How about 3 orders of magnitude less conductive? The fact is that in this application, 30 times better than soil is adequate for the water to behave a lot more like copper than like soil.

A modest system of radials in soil looks like very, very small cross sections of copper (remember the skin depth in copper!) separated by very large regions of soil.

Out of curiosity, I altered the conductivity of the water in my computer model. Dropping it by a factor of 10 at DC (about 3 at RF) results in a reduction of about one dB in field strength, or about 25% in efficiency when using a single ground wire. So salt water has just about the minimum conductivity you can get by with if you want really good efficiency with a single ground wire.

> Where am I going astray?

In oversimplifying the problem and using analogies which aren't quite right.

From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <WqidnSFzY9e-G-XZRVnyhA@bt.com>
Source record: 58700

The permittivity, K, of water is about 80.

The relative velocity of propagation along a wire immersed in water is about VF = 1/Sqrt(K) = 0.11

At a frequency of 7.5 MHz, a 1/4-wavelength of wire immersed in water is only 1.1 metres = 43 inches long.

Furthermore, in salt sea water, considering a wire as a transmission line, dielectric loss is so high there is little or no current flowing at the end of a quarterwave radial wire. Longer wires can be disregarded because they carry no current.

So, at 7.5 MHz, there is no point in considering a system which has more than a radius of 1.1 metres. At higher frequencies the radius is even less.

A copper coin, 1" in diameter, immersed in a large volume of salt water, has an impedance low enough to be used as an efficient ground for a 1/4-wave HF vertical antenna. It is limited by its power handling capacity.

I have made measurements years ago but have no records as I didn't attach any importance to them at the time. And still don't.

Unpolluted, clean, fresh pond water, is a different kettle of fish. Permittivity is still about 80 but the resistivity is very much greater. About 1000 ohm-metres is a reasonable value.

Reg.

Interesting info, Reg.

I also made some kitchen table-top saltwater measurements about a year ago, but at much lower frequencies than you discuss. My measurements are not handy at the moment, but they don't comport with yours. I utilized a variety of electrode geometries: concentric, 4 pole, parallel plate, etc. Measurements of electric field strength, conductivity, path conductance, etc. are not difficult but interpretation of the data stumped me.

As you remember, the conductance of a saltwater path is a direct function of the path's cross-sectional area. A penny doesn't produce much of a cross-sectional area at its end of the path. Maybe your pennies are better than ours, Certainly worth more.

When the material is conductive, like salt water, you also have to consider the conductivity in determining velocity factor. The velocity factor in salt water is 0.0128 at 7.5 MHz, 0.0175 at 14 MHz (based on conductivity of 5 S/m and dielectric constant of 81).

Incidentally, you can get this information directly from EZNEC, including the demo program. Select a real ground type, then find the velocity factor, skin depth, and other information in Utilities/Ground Info.

Hi Chuck

So what would be the best size cross sectional area to achieve a close to perfect RF ground from 1 to 30 mhz over sea water? Considering things like corrosion, fowling, growth on the plate over time and any other factors that would deteriorate the effectiveness of this connection. You would want adequate safety margin when using this kind of simple direct contact.

I dont have NEC4 is it too much to ask you to run the model. Radials
over sea water versus a direct connection?

Theres no easy way of making sure that the wires will submerge
precisely or close to the ideal skin depth. The loading and heeling of
the yacht would affect this depending on the sailing position wind
speed and other factors. The motion of the waves and swell conditions
will also be another variable. It would work great when you anchored.

Well if you read the many sailing web pages and the Icom marine
guides they all advocate installing your RF ground system well below
the skin depth of salt water. They also advocate bonding all your on
board metals to submerged objects like the keel and copper ground
shoes, which is clearly wrong.

A yacht with elevated radials installed below the deck would radiate a
better signal in my view. However what constitutes an effective radial
system over seawater for frequencies between 1 and 30 mhz using a
random wire backstay antenna versus a direct connection to sea water i

cant answer without the modeling software.

Hello Bob,

Sorry, but I'm not able to answer your question as I'm still struggling to find an appropriate mental construct. For the moment, I'm suspending disbelief, as they say.

Roy, W7EL, has reported model results showing that a wire (probably a few millimeters in diameter) only one foot long will produce near-perfect (my words) results.

The greater the cross-sectional area, the better, of course, but it would seem not to be a critical factor based on what both Roy and Reg reported, A one inch diameter copper pipe would probably give you some margin based on those reports. Make it a couple of feet long and slip it through six inches or so of one of those foam "noodles" the kids use when swimming. That will keep it afloat, ensure it is visible, and protect the hull from damage when it collides. Remember that you will have to figure out how to attach this pipe to your tuner. In a lot of installations, that will mean six feet or more of wire (from tuner to pipe) hanging over the gunwale. That wire is effectively part of your antenna, and it will radiate. For convenience, it would make sense to let the pipe float away from the hull by six feet or so, but that makes the connecting wire even longer. If you hang something like that over the side you'll doubtless want to secure it with some kind of UV resistant line to take the strain off the wire, especially when under way (ugh!).

On some boats, using the stainless rudder shaft could be a better solution if you can attach to it. It is often near the surface of the water. On other boats, the rudder shaft exits the hull well below sea level and that probably wouldn't work.

Experiment by all means, and if you go the copper pipe route, just
remember that your zinc will be protecting whatever copper you immerse.
If you use a lot of copper (like a 1 foot diameter by 1 foot long
cylinder made of copper flashing with lots of holes drilled in it),
expect accelerated depletion of zinc.

Good luck.

Chuck

Hi Bob,

As I offered some time ago, how deep is fairly immaterial and your dismissal of "many sailing web pages, Icom" and so on to then come to the conclusion that they are "clearly wrong" is not quite so clear why.

There are only two paths to that ground system well below the skin depth of salt water:
(1) Through the water;
(2) Through a lot of air within the boat.

For (1), that already takes care of itself, but is a very odd method to getting to that dynaplate. Besides, a wire tacked to the outside of the hull, or worse simple thrashing in the surf, has got to add to drag. Following this wet path automatically snubs how much current will make it to the plate anyway. As Reggie offers, after 40 inches at 7MHz it is immaterial and that wet path to the plate makes the plate simply a tie-point. In short, you have to penetrate that skin depth to get beneath it. Penetrating it solves the "problem" of going too deep.

For (2), what do you stand to lose with a deeper connection that is approached through the interior of the boat? This is a matter of matching characteristics, which lead to issues of loss. You have the same connection loss anyway you look at it.

So, what value is there in these page's recommendations? It insures a connection.

Of course, I could be wrong. I've only had experience in electronics on Big Gray Boats in salt water, or in Big Gray Submarines beneath salt water. Ground was everywhere and death as far away as a power lead (several dozen nuclear warheads were only slightly further away).

Hi Ben,

Two things wrong with this:
1) He's in Ankara (West, not East);
B) We get the same the same urgent requests from American students in
Florida (and all points north and west of there too).

The end of term is coming up.

I don't think so. It is not conductive.

Maybe conductive epoxy would work, tho.

This would not be going on the threads. Rather, it has to bond the
[unthreaded] outside of female threaded collar to the antenna tubing.

I) I guess if I'm going to generalize I'd better pay more attention.

Two) I still think there's a cultural/language issue going on. I get
questions all the time from people about projects on my web page.
Almost all of the ones from people with Chinese/Indian sounding
names (hard to tell where they're from if they don't volunteer it and
they're using Yahoo mail!) are demanding. Here's the first example
in my inbox, although this one is relatively tame:

] i'm very interesting about this project because i want to use this simple card
] for a simple interface with the hardware outside for example for a simple
] input/output. i want to ask about the schematic of this project. Can you help
] me for this. i wait your answer as soon as possible.

In contrast, American students seem to just cut and paste requirements
from the handout. ;-)

No, but I know what you're talking about. (The demo I did for class was a desktop affair -- kept in a suitcase between classes) You're probably referring to the model range(s) at Naval Ocean Systems Center (NOSC) on Point Loma. NOSC was consolidated, I think, into Space and Naval Warfare Systems Center, San Diego.

For those not familiar with this process, they used brass ship models, both existing and proposed, built to 1/48 scale. They were on a lead (Pb) "sea" at least 100 feet across. At the center of the "sea" was a turntable, on which the model could present any aspect to the tower you refer to. The tower supported a log periodic antenna which could be raised along a curved arc from the horizon up to the zenith, overhead the model. Picture about halfway down the page at

http://www.spawar.navy.mil/sti/publications/pubs/td/1940/photos/

The model ship was fitted with scale antennas, complete with coax that ran down through the turntable and into the control room. For any given antenna and location on the model, the engineers could get a three-dimension Antenna Radiation Pattern at scale for a good idea of how it would work in the real world. ... and I understand it was quite reliable. 96 MHz scale was 2 MHz real-world, and so on. I think the LPA did all the transmitting, but I'm not positive.

I got a guided tour of the range once in the 1980's when I was in their building for an unrelated conference. (It was more interesting than parts of the conference, but that's another story.) I wonder, do they still model antennas this way?

A few of the brass models were regularly on display, visible from the road about ten feet behind the fence, for many years. It has been five years since I did any work on Point Loma and I don't know if any models are still

in public view.

Hi Ben,

My professional page got me inquiries from a private investigation of the TWA flight 800 crash. But I got something in return, a graphic chart of all the flight control settings from take-off until the lights went out. The questions I got from the lawyer went deeper than any student's final project.

Hi Tom,

The stuff you've got there is nice, but the accompanying discussion has very little context if you haven't been part of the threads here. In fact, and only from my recollection, your descriptions were better described in this group. At the page however, I really don't see what you are trying to do in the "How does a shield work." The "Faraday Screens" was interesting. It would be more interesting with the data you imply, but that is hardly necessary as there is so much literature in how it works.

Sure. How many, how high, and how long? The foot-long wire produces efficiency of virtually unmeasurably close to 100%. So radials can't be significantly better. What sort of efficiency are you expecting from the radials?

Why can't you extend a wire or strip all around your boat, or make it several feet long? There's no penalty for having it extend beyond several skin depths. Fishermen somehow manage to keep their lines and nets in the water -- surely you can work out a way to keep a wire in the water.

To illustrate the order of magnitude of the effects :

An ideal shape of ground electrode is a hemisphere, of diameter D metres, pressed into the soil, flush with the soil surface..

Its resistance to the soil is easily proved and calculated :

R = S / Pi / D ohms,

where S is the soil's resistivity in ohm-metres and D is the diameter in metres. Pi = 3.14. The metric system is by far the most simple.

The resistivity of salt sea water is 0.22 ohm-metres, constant wherever you may sample and test. Unaffected by the melting of the glaciers.

So with a diameter of 0.22 metres = 9 inches, the electrode resistance = 1 ohm. Low enough?

If the ground electrode is a ball with diameter = 9 inches, immersed in sea water at a sensible depth, then the electrode resistance will be halved.

At radio frequencies the impedance of the connection to ground will be that of the connecting wire only, even before the resistance of the connecting wire to the water is taken into account. The high permittivity of water will also tend to decrease impedance at RF.

Another illustration, following Lord Kelvin :

The resistance of a ground rod to soil is given by :

R = S / 2 / Pi / L * ArcSinh(2 * L / D) ohms,

where S = soil resistivity, L = rod length in metres and D is rod diameter. ArcSinh is the inverse hyperbolic Sine function you will find on your pocket scientific calculators.

So in sea water, at low frequencies, a rod 12 inches in length and a diameter of 1 inch will have a resistance of 1.2 ohms. At HF, because of the very low propagation velocity in water, propagation effects predominate and the rod must be considered as a very lossy transmission line. But its impedance to ground is still very low because Zo is very small.

So the hull of a metal boat makes an excellent ground. Just connect to it with an alligator clip at the end of a length of wire and stop worrying about it.

By the way, the practical units of resistivity in ohm-metres should be much preferred to the academic units of milli-Siemens. When dealing with milli-Siemens I find I have to stand on my head and look backwards.

1 milli-Siemens = 1000 ohm-metres.

The clock tells me it's 7.30 in the morning in Birmingham, the idle, depressed ex-industrial city of the Midlands, where there used to be 10,000 factories, now superceded by the hardworking Chinese, and I'm already half way down a bottle of Spanish Campaneo red. Hic!

It's a technology race, and the instructors are well ahead.

Dissertations can now be scanned by Google-type software that looks for copying. Whatever literature resources the student could have used, the department has access to the same and more.

A friend told of a recent example of a final year dissertation on 2.4GHz LNA design. The software easily found the un-referenced Agilent Application Note that the student had copied. They had already been warned...

That's not quite accurate.

The mutual coupling and effect of additional elements can shift
frequency in any dorection depending on parasitic element tuning. The
effect isn't caused by the capacitance of additional elements, it is
caused by the complex interaction or reradiated power arrivibng with a
time delay back at the original source.

This is why, with various element tuning and spacings, feed impedance
of a Yagi can change all over the map.

Same for dipole height, the reflected wave from the earth will change
feed impedance as well as shift resonant frequency.

Probably only the engineer at Rohn would know.

It may not be as a safety feature when mating, because Rohn 55 uses
two bolts exactly the same size in each leg. Most likely it is a stress
rating issue, and that's all the bolt size needed to do the job.

That hole in the water is pretty important. It not only allows the plate a few feet down on the hull to make a good connection, it also makes the boat float better.

I'm sure sooner or later someone will tell you there isn't a hole because where they put their boat, because when they take the boat out of the water they can find the hole.

An arithmetical correction. I forgot to divide by Pi.

The resistance of a hemispherical electrode, 9 inches diameter, in salt sea water, is even smaller. It is only 0.32 ohms.

Incidentally. the resistance of a flat circular disk of diameter D metres, in contact with the soil surface, is given by :

R = S / 2 / D ohms,

where S = soil resistivity in ohm-metres.

In sea water, a disk of 12 inches diameter has a resistance of 0.37 ohms. Which is negligible in comparison with the radiation resistance of a 1/4-wave vertical antenna of 36 ohms.

Careful readers should make a note of these hints and tips, free to USA citizens, in their notebooks.

My own notebooks extend from volumes A to letter S. I'm wondering who to leave them to in my Will & Last Testament.

The first time I encountered 25G, that particular design feature didn't
prevent me from using all the small bolts in the box. The bigger ones
were obviously meant for something else.

Americans are apparently born knowing all about Rohn tower sections; but
Englishmen need to be properly introduced.

Same for dipole length, the reflected wave from the ends of the
dipole will change feed impedance as well as shift resonant
frequency.

The feedpoint impedance of any standing wave antenna is the
superposition of all the E-field voltages divided by the
superposition of all the H-field currents and is the result
of the interference pattern. Doing anything to change any of
the voltage or current components will change the feedpoint
impedance.

Reg, FYI: "NAPA, Calif. - French and California winemakers marked the 30th anniversary of the storied Paris tasting with another sip-and-spit showdown. California won - and by more than a nose. Native wines took the top five of 10 spots, with a 1971 Ridge Monte Bello cabernet sauvignon from the Santa Cruz mountains coming out on top Wednesday."

Not usually. They fill the hole in the water with so much money they
never notice anything else.
:-)

Roy, after re-reading the above comment this morning, I realized you probably meant that RF currents flowing to the plate could simply travel from the plate along the hull/water boundary to the water line, and from there, change direction and travel over the water's surface. Much as currents would travel up and down the surface of a large ocean wave (except for hull/water vs. air/water boundary differences).

If so, then your model results show the Dynaplate's location is not critical as long as it is attached to the hull and it need not be mounted at the waterline?

Is my reading of your comment correct?

Thanks.

73,
Chuck

I visited and was given a tour of that site some years ago, when it was NRaD. They were also doing computer modeling with NEC-4 of the same ships and structures they were measuring. One of the engineers told me that when the results from the computer model disagreed with measurements from the physical model, they'd learned to believe the computer model.

This was a statement of just how difficult it is to make really good measurements, even when you have the best equipment. Accurate computer modeling of complex structures is no trivial task, either, but it was something they were very good at.

Even a semantically-sensitive AI-type context checker would have had
problems with that one. "Water lever" is an obvious reference to the
float-and-valve arrangement in a toilet's water tank, and everybody
(including good AI systems) know very well that boats are the best
invention ever made for flushing money down a toilet.

Ok, that clears it up. You said originally lower, I said no particular
direction, so the answer is the second, but you probably meant it could
go either way, correct?

I also normally work with YO on yagis, so I really don't pay much
attention to the resonance, just the real portion of the impedance.
Then I fix it when I build the DE and match.

Dear Ian:
The worst case that I encountered was the finding of a direct copy of my own work in a student's thesis! I was not amused!

On the other hand, I recently was faculty advisor on a thesis of exceptional quality and originality. The student had performed some valuable and original work with nano-technology. The student's care in crediting each and every idea that was used and every person who helped (including skilled technicians) was a model of what should be done. The best students know, and acknowledge, their antecedents, mentors and then delineate what they have done that is new.

I offer the above as an example that not all is lost.

Warm regards, Mac N8TT

Oh, indeed it isn't. The friend who told me about the copy-detection
software had spent 20 years of his life as a rock musician, but is now
headed for a First Class honours degree in RF Engineering. Needless to
say, he's an active ham.

Well well...

Whatever one believes and/or thinks about the EH-Antenna, Ted Hart, the creator and the patent holder, is honest enough to release the full design information to the ham community - to hate or to love.

The method of selling sealed envelopes is - at the best regrettable and at worst, something really different.

As the EH-Antenna is targeted to the commercial world - this antenna is an obvious way of making money out of the non-commercial hams.

I think the judgement are coming down hard on you Felix and I have to agree on this judgement. Again, nothing personal but maybe a very much middle European way of selling. As the Ham world is mainly Anglo-Saxon - it just doesn't work! I suggest you do as the EH-Antenna Inc, release the full info for homebrewers and sell a ready made version to the turn-key amateurs instead!

Cheers

Dan / M0DFI

One of the advantages of selling the ready made version is to ward off
those who don't follow construction details carefully and unfairly
generate negative reports about the antenna. From what I gather, it
is very inexpensive to build which lends to room for a large enough
markup to gain some profit.

The reports are pretty lackluster I'd say... A 1/2 dipole would have
trounced that thing... It might be small, but so is the performance
judging from your reports. If I was working regional distances like
that and got 57-58 reports, I'd be wondering who cut my antenna
down.. :/

Reg, G4FGQ wrote:
"At radio fgrequencies the impedance of the connection to ground will be that of the connecting wire only, even before the resistance of the connecting wire to the water is taken into account."

In general, Reg is correct.

I`ve installed a marine radio on a yacht, engine powered not the sailing kind. It worked well as expected and the owner paid promptly. I`ve also installed radios of various types in many vessels including large ones used on the high seas and small work boats serving the near offshore. But, I never installed an antenna using radials on a boat or ship. Radials can be hazardous to eyes and body parts at sea. For VHF, a 1/2-wave coaxial antenna has the same gain as a ground plane but needs no radials. For HF, it`s easy and effective to use a loaded vertical antenna against the sea as a return path.

Best regards, Richard Harrison, K5WZI

If this is a homework/exam question... well, in that case, stop reading and go hit your books, OK? You'll be better off in the long run if you learn to figure such things out for yourself.

If the tower isn't too far away (too close to the visual horizon) then you can probably treat the distance between you and the tower as a flat, horizontal surface - that is, ignore the curvature of the earth.

If that's the case, then you can calculate the distance using trig if you know the distance to the tower and the angular height of the tower. You can measure the latter with a plastic protractor.

If the road you're on is straight, there's a relatively easy way to figure out how far away the tower is from the road. Do the following:

- Drive along the road until the tower is directly off to one side - the line from you to the tower is perpendicular to the road.

- Use a protractor to measure the number of vertical degrees that the tower covers.

- Make a note of the odometer reading.

- Drive straight, on the road, until you have to look backwards at a 45 degree angle to see the base of the tower, and then stop. Use the protractor to confirm the angle, so you know right where to stop.

- Take another look at the odometer.

- The difference between the two odometer readings - that is, the distance you've driven from your starting point to your stopping point - is identical to the distance from the starting point to the tower.

- Multiply the distance you drive, by the tangent of the angle which describes the tower's apparent height at the starting point. This will be the height of the tower, plus/minus whatever errors crept in to your measurements.

- Go through the geometry to truly understand why this works.

- Use a fluorite-lens transit and a properly charged flux capacitor to confirm that there are no thermal or gravitational anomalies which might have distorted the light or the distance.

If the road is curved, or the land is hilly, or the tower is far enough away towards the horizon, then you'll need a more complex approach... e.g. go measure it, or call the owner and ask, or do a lookup in government records (FCC) to find the operating license permits for the radios on the tower.

there are lots of ways depending on how close you can get to the tower and what is around it. one simple one, if you can see the base and a person or building near it hold your arm out and use a finger or pencil or something to measure the person or building then step that up the tower to see how many times taller the tower is.

Short of using geometry, I can only think of one other way. research
all the cell tower manufacturing companies' catalogs and get to know
their model numbers and sizes. Then when you recognize a particular
model, you will know how tall it is.

Here's a technique that I learned 60 years ago in Cub Scouts.
With your back to the tower, bend over and look at the tower between
your legs. Walk backwards toward the tower until you can't see the
top of the tower. The distance that you are from the tower is close to
the height of the tower.

How about a design that is small in size, loads the feedline, lights up
the shack, and fries my pacemaker? RF has got to go somewhere! It is a
good bet that if the military and commercial users have not or do not
accept the super design, then I think I will save my $ for the more
accepted, tried and true antenna.
New ideas need to be consistant with the accepted laws of physics
unless what is being proposed is so radical that it breaks new ground.
At that point it is the job of the inventor to lay out the theory and
application for peer review. Otherwise, we spend a lot of time shooting
the bull.

How does a copper wire behave when submerged in salt water? Won't it corrode
rapidly, so that you don't get a metal to salt water connection, but
a capacitive coupling across copper oxide?

Not a rhetorical question, btw. I really don't know the answer.

The only other thing you missed Dave, is dropping and measuring a plumb line from a hot air baloon while stationary above the tower. Of course the FCC will want you to calculate RF exposure to those in the baloon, but this is another low tec / low math approach! Make sure you bring a sliderule since the RF might cook a calculator. Oh yes, you do need to know how to use that sliderule as well. WB3HUH

Measure the length of the shadow, and record the time. Look up what the
height of the sun was at that pouint in time from tables, and use geometry.

The original poster didn't indicate he could get to the tower, but if he could, there's a better way than above that doesn't require "tables". .... simply measure the length of the tower's shadow. Then with a yardstick, or equivilent, measure the length of the vertical yardsitck's shadow. You now know the height and shadow length of the yardstick. You also know the shadow length of the tower. The two are proportional.

The height of the yardstick divided by the length of its shadow is equal to the height of the tower divided by the length of its shadow. A simple algebraic expression ... easy to solve for the height of the tower.

Ask the HOA - They will measure it to the microinch, then tear it down.
Ask the City (County) Engineer -- they will respond "Ain't no tower there"

Seriously -- how about this one

Wait for a sunny day! Measure your shadow. Stanley tools makes a device for this (;-). Measure the tower's shadow. Calculate the tower height using the following:

Height of tree Your height

=

Tree's shadow Your shadow

Alternatively, you can place a calibrated pole upright and measure it's shadow in place of measuring your shadow.

About 2200 years ago a greek guy - Eratosthenes used geometry to estimate the circumference of the Earth. Dog gone if he didn't come close!

A Boy Scout technique from 55 years ago comes to mind.

It requires one arm, one thumb, and two eyes.

It needs a little geometry associated with similar triangles.

Extend your arm with one eye closed and your thumb at one extreme of what you want to estimate. Open that eye and close the other. Estimate the difference in distance between the two observations. Multiply that distance by 10. Not bad for a first 'gesstimate'.

BTW, do the Boy Scout still teach this?

If in the U.S.A., contact the FCC and get the information from their
database. Elsewise, contact the wireless regulatory agency of the
country that the tower is located in.

In the USA if it has a light on it then it is over 200 FT tall. If there is no light on the tower it is less than 200ft tall. 200 ft is the magic number for the FAA and the FCC for tower lighting.
If you can see the section joins then count them an mult by 20 ft. 20 ft is the height of the average tower section. Your tower could use 30 or 40 ft sections though. You will have to inspect the tower up close to estimate the height of a section.

Almost right, over 200 feet or close to an airport or heliport, in
which case the max unlighted height slopes to zero at the airport
and follows a slope that depends on the type of airport.

Correct.... But most cell towers are not near airports.

Correct... But the protected area is 12.2 kilometers in diameter which
means a good number are.

3338. Motor for remote controlled tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-29 18:47:24 UTC
From: Ed <Huckleberry_REMOVE_@bigvalley.net>
Message-ID: <Xns97D2782F52835spectrumhogstarbandn@198.186.192.196>

I'm considering building a remote controlled balanced tuner. Some type
of low RPM motor 12V reversable motor is what I have in mind to accomplish
the tuning. I will have two fairly hefty variable caps to turn along with
a moderatly sized roller inductor.

Can anyone here recommend a particular type motor, and a reasonable
source for the the type of motors I need? Tnx.

That's a tough one, Towers get taller the closer you get to them. You need
to contact the manufacturer or installer.

What you're probably going to want is a gearhead motor, with a relatively low RPM rating (1 - 4 RPM is probably the right sort of range). These have plenty of torque, and you can probably slow down the rotation even further by using a lower DC voltage or by pulse-width modulating a 12 VDC drive.

It'd be worth checking out a 24 VDC gearhead motor - it would run at a slow speed on 12 VDC but might well have plenty of torque to rotate a cap or inductor.

You'll need some sort of external limit-switch arrangement (e.g. lever-type microswitches with bypass diodes) to cut off the drive current when the inductor reaches the end of its range - gearhead motors have more than enough torque to drive the inductor into its stops and damage it.

> Can anyone here recommend a particular type motor, and a reasonable
>source for the the type of motors I need? Tnx.

Check the various surplus outfits on-line: All Electronics, Ocean State Electronics, Electronics Goldmine, etc.. Going prices for DC gearhead motors seem to be in the $10-$15 range. Goldmine has some small gearhead motors (3 RPM at 6 volts) for $12, which might do the job.

Also, check local surplus-machinery stores if there are any in your area, and local hamfests/swapmeets. I picked up a bunch of 24 VDC gearhead motors for a buck apiece at one of the latter.

Here is an example of a tall, top loaded tower:

http://www.bslb.org/photo/20050813/nikon/images/DSC_1806.jpg

http://www.bslb.org/photo/20050813/nikon/images/DSC_1785.jpg

Looks like SSV tower with 20 foot sections. I estimate that the near tower
is a little over 200 feet high. Also looks like brackish water in the
foreground and far west location.

The copper alloys widely used in wires are quite resistant to corrosion.
Even when immersed in pure seawater, their corrosion rate there is on
the order of 0.025 mm/year. Unfortunately polluted waters can increase
that rate.

The metal to water interface may indeed be affected by the corrosion
layer. This problem is frequently seen by electricians when installing
grounding rods in the earth. However, I imagine the capacitance in this
case would provide sufficient coupling at RF so that it would not be a
problem. Biofouling might be of greater concern if corrosion does not
occur fast enough.

3345. Interlacing 2 meter and 70 cm beams

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-30 02:03:46 UTC
From: VK3XL <VK3XL.28lp1m@news.radiobanter.com>
Message-ID: <VK3XL.28lp1m@news.radiobanter.com>
Source record: 58589

Hi all, I am currently building a new 2 meter beam for SSB. I am using the DL6WU design on a 6 meter boom. While working on the antenna last night a thought struck me "why not interlace a 70 cm beam on the same boom"?
so here is the question, does any one have any data on interaced beams in particular the degredation of performance of the equivelent monoband yagis.
There are a number of reasons that this interlaced beam idea is appealing to me (mostly mechanical) but I am not sure how badly the gain may be effected. Does anyone have real data on the issue?
many thanks
Mike

This can be done using a barometer.

Drop the barometer from the top of the tower, timing the fall.
The tower height in feet is 16 times the square of the time in seconds.

Alternatively, offer to give the barometer to the tower's owner in exchange
for telling you the height of the tower.

There is a local repeater system here that was put together by an impoverished college student many years ago. He didn't have much money for duplexers, but he did have the gift of persuasion. He was able to talk his way on to 4 towers scattered about town. He has transmitters and receivers for 6m, 2m, 1.25m, and 75cm spread over the four towers, all cross-linked. No tower has a transmitter and a receiver on the same band. Each tower is 15 to 20 miles from the next tower.

Some help: I saw one for sale at HRO a few years ago. Might have been this
one:

http://www.eham.net/reviews/detail/3297

Note also that many VHF TV antennas are this way; the low-band elements for
55 - 88 MHz share the boom with the high band elements for 172 - 216 MHz.

These two bands are approximately in a 1 : 3 ratio, as are 2M & 70cm.

> 73,
> Chuck
> NT3G

I don't know about corrosion resistance, but the copper wire used in electrical conductors is very high purity. This is needed since any contaminants reduce the conductivity. Here are a few quick references:

Copper is made with different purities depending on the application. The highest grade copper is electrical grade. It is 99.99% pure and is used for electrical cables because it has the best electrical conductivity. Electrical grade scrap must never be mixed with any of the lower purity grades such as plumbing tube scrap. This contains too much phosphorus which drastically reduces the electrical conductivity.

The lower grades of scrap can be used to make copper alloys or chemicals. The copper sulphate you use in your school laboratory has probably been made with scrap copper.

http://www.schoolscience.co.uk/content/3/chemistry/copper/copch32pg3.html

Copper Facts

Electrical

Copper is the standard benchmark for electrical conductivity. It conducts electrical current better than any other metal except silver.

Copper is routinely refined to 99.98% purity (even more pure than Ivory Soap) before it is acceptable for many electrical applications.

Number 12 (AWG) copper wire is the most common size used for branch circuit wiring in buildings. The amount of copper products consumed in the U.S.A. this past year would make a size 12 wire that could encircle the Earth 2,630 times or make 140 round trips to the Moon.

http://www.copper.org/education/c-facts/c-electrical.html

Regards,

Mike Monett

Thanks for the reply. All very interesting, but I am thinking of
something a bit bigger ie 12 elements on 2 meters on a 6 meter long
boom and up to 27 elements on 70 cm on the same boom. I fear that
because 70 cm is almost exactly the 3 rd harmonic of 2 that the 2meter
elements will act as unwanted directors in the 70 cm beam, any thoughts
welcome.....
Mike

Copper piping and water jackets are often badly corroded when decaying plant and animal mater and sediment are dormant in the pipe. This is likely to be more troublesome in marinas and harbors than in the open ocean (Sargasso Sea excepted, maybe).

"Particularly detrimental are sulfate-reducing bacteria in bottom mud and sediment and on the natural sulfates in seawater." from "The Boatowner's Guide to Corrosion" by Everett Collier.

3355. RF grounding methods for sailboats: A Summary

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-30 13:21:56 UTC
From: chuck <nospam@nospam.net>
Message-ID: <1148994725_36063@sp6iad.superfeed.net>
Source record: 58595

This is a distillation of several recent postings and other readily available information on securing a good RF "ground" for a vertical antenna on a plastic or wood sailboat. The basis for each method was either reported model results or a presumed "organizational authority" on the subject (i.e., ARRL, Icom, and SGC).

No ranking or recommendation was intended.

If anyone spots any errors of fact or significant omissions, I'd welcome appropriate "recalibration". Thanks in advance.

1) Grounding plates

Will not work if submerged as much as four feet, but will work as near-perfect if at the waterline, and may work if attached to hull even when submerged four feet (awaiting clarification from Roy, W7EL). In fresh water or low-conductivity water, a ground plate may not function acceptably. Sometimes used in combination with #4 below. Recommended only "as a last resort" by Icom.

2) Wire in water

A one-foot length of wire immersed near water surface is sufficient for near-perfect results based on W7EL's NEC-4 model results. Assumed performance is similar to grounding plate.

3) Radials

Even shortened (loaded) radials elevated over seawater work as near-perfect based on N6LF's NEC-4 modeling. Objections to radials are safety (high-voltage insulation notwithstanding), tripping hazard, undesirable RF coupling, and the necessity of either tuning the radial(s) or installing multiple 1/4 wavelength wires. Radials will be useful even over fresh water or when boat is on land. Single radials can provide significant near-vertical radiation which may be useful, but at the cost of reduced radiation from the vertical radiator. Considered a viable alternative by Icom but not recommended by ARRL.

4) Counterpoise (i.e., mast, forestay, shrouds, lifelines, engine, metal tanks, 100 square feet of copper, keel, rudder, etc. bonded together)

One of the traditional approaches to marine SSB installations on plastic and wood sailboats. The mast and rigging often provide the equivalent of ~200 lineal feet of counterpoise wire above deck with additional metal structures connected on and below deck. Sometimes used in combination with a grounding plate. If copper is placed inside hull below waterline, useful capacitive coupling to the water may occur. Will work over fresh

water and on land. This is the method recommended in the ARRL Antenna Book, where radials, as the only considered alternative, are discouraged in their discussion for the reasons stated in #3. This type of counterpoise is also the approach recommended by both Icom and SGC.

5) OCF dipole w/horizontal component along deck

Not commonly used, but obviates the need for multiple resonant radials. Analyzed by W4RNL. Usually requires a current choke in the coax from tuner to rig to reduce undesired RF coupling. Suffers from some of the same objections listed for radials; will also provide some near-vertical radiation. Will work over fresh water and on land.

Is that where it stands, folks?

73,

Chuck,

You are all making a song and dance about it.

Whatever the ground electrode system happens to be, the impedance to Earth cannot possibly be less than the series impedance of the connecting lead. Which can be quite high at HF.

In my opinion, the most effective ground will always be a short, thick, direct connection from the radio equipment to the internal hull of a metal boat.

If you like, you can connect whatever else you have in mind in parallel with it, probably at the other end of a long lead, and it won't make the slightest improvement in performance.

Just use your loafs. And Happy sailing!

Reg, G4FGQ.

One method of solving that problem is to orient the 2m elements
at right angles to the 70cm elements. Of course, if you don't
rotate the antenna by 90 degrees between bands, you would
lose 3 dB on both bands (assuming you want horizontal
polarization on both bands).

For use in salt water, a number of Cu alloys have "excellent" corrosion resistance. Among those that are available are the Admiralty Brasses (C44300 with As or C44500 with P). They have about 25% conductivity wrt to soft Cu. (Brass is mostly Cu and Zn.)

Phosphor Bronze (C52100) is also a candidate with 13% conductivity. This is particularly good for antenna wire use.

Pure Cu is expressed as having "good" resistance.

Find a thin plate of Admiralty brass and bond Cu or phosphor bronze wire to the plate. Put the assembly into the water as "ground" and you are done.

I think that you'll not really know what happens unless you model the whole thing.

You might be able to tweak the whole thing for best performance in software then. There are likely too many things you'd have to change to do a manual optimization with the number of elements you're talking about, but at least you'll know what the pattern is.

I did this for a 2m/432 combo where I hung the 432 4 element off the nose of the 2m 5 element, but, admittedly, this was a MUCH easier situation, as the 432 beam by itself had 20dB F/B. The pattern was changed by proximity to the 2m antenna, but it was an improvement.

I adjusted the spacing of the 432 beam for the best F/B and the 2m beam ignored the 432 entirely.

Hobby Engineering has a bunch of gearmotors...

http://www.hobbyengineering.com/SectionM.html#IX1415

I bought three to remote my tuner. Plenty of torque to turn the caps and inductor switch in a "1500W" MFJ tuner. They're only $5.50 apiece new.

They're also all-plastic gearboxes and output shafts, so you don't have to worry about insulating shaft couplers, etc.

My gut feeling is that the ones I bought (Gear Motor 9: Right Angle Shaft) could be a bit undersized to turn a roller inductor, especially since you probably want to go a bit faster.

http://www.n3ox.net/projects/servo has info about my remote tuner.

Yes, but who's to say where the
connecting lead begins. Simply imagine
the antenna extending all the way to the
ground electrode system and the tuner
inserted, say four feet above it. The
tuner may need some RF choking, of
course, but ground lead impedance is now
near zero ohms.

Simply "getting" the answer from google is not wrong or unethical - any more than looking up the answer in a textbook.

It is what you do with it after you get it. that is the issue. I do my research in textbooks, reference volumes, and google. It's all good. As long as it is correct.

Some of this creeping codgerism sounds like the old rants against calculators..... and I'll bet slide rules before that! ;^)

True, except most of the folks discussing Rf Grounds here aren't
working with metal hulled vessels. They are dealing with wood or
plastic (Fiberglass) hulls, where an effective RF Ground is
significantly harder to build.

>thanks in advance. cl.

Although you are going to get a lot of answers the killer is that KISS
which leaves an answer of, no...no really, BUT depending on your math
skills you can come up with a rough approximation.

The accuracy depends on being close enough to get a reasonable angle
between the ground and top of the tower. That depends on you and the
tower being at the same height. You can determine the distance to the
tower by starting with the road at right angles to the tower and
driving a measured distance and again using trig to find the distance
to the tower, but this depends on things not only being level but the
road being straight and level and your ability to find a point where
the road is at a right angle to the tower.

So rephrased you are using right triangles to find the distance to the
tower and based on that another right triangle to find the height.
(time to study your trig functions).

Depending on your ability to determine the location of the right
angle, how level the land, the distance to the tower, and your angle
measuring ability you could come up with an error between a few
percent and as much as 20% or even more.

But you're missing, or trying to
circumvent, the most interesting aspect
of the problem. It's the one which
highlights the very core of our
disagreement. The energy stored in the
line, remains stored in the line as long
as steady state is maintained without a
single Joule of additional energy moving
into or out of the line. To me, this
illustrates clearly how the fields at
the impedance interfaces of a matching
transformer can be maintained without
requiring multiple rereflections of
energy. I'm hoping some day you'll see
it too.

> So is this your proof that Joules of energy are likewise reflected from
> antireflective surfaces?

No, the two subjects are conceptually only distantly related so your
posting is a diverting of the above issue - changing the subject back
to an earlier thread:

Every impedance discontinuity causes reflections. An antireflective
surface is an impedance discontinuity, i.e. a change in the index of
refraction between two mediums. If properly designed, the anti-reflective
surface causes 100% destructive interference between the internal and
external reflections each of which contain joules of energy. It is easy to
prove
that the internal reflection contains joules of energy. If the external
reflection
didn't contain any energy, then destructive interference would not be
possible. Therefore, both reflections associated with an antireflective
surface must contain an equal magnitude of joules.

In his QEX article, Dr. Best gave us the physics equation that governs
100% destructive interference: Ptotal = P1 + P2 - SQRT(P1*P2).
Assuming that power cannot exist without energy, if the energy in P1
equals the energy in P2 and the associated waves are 180 degrees out
of phase, then of course 100% destructive interference occurs at the
antireflective surface. That's how antireflective surfaces and Z0-matches
work.

Richard,

I'm pretty sure steady state isn't
achieved in that short a time when there
are significant reflections on a line
that long.

Consider this. Initially, forward power
from a 100 Joule per second source is,
naturally, just 100 Joules per second.
After one second, (the first second in
particular), there should be 100 Joules
on the line.

It follows that the initial reflection
would be 50 watts. When we assume that
everything is re-reflected from the
source, then at two seconds the forward
power at the front of the line would be
150 watts. At four seconds, 175 watts;
six seconds, 187.5; eight seconds,
193.75, and so on.

When the number finally reaches 200
Joules per second at the load, the
reflected power would have become 100
Joules per second back at the source one
second earlier. At that point we can
multiply the sum of forward and
reflected power by the length of the
line in seconds and gleefully announce
that 300 Joules are being/have been
stored in/on/at the xmission line.

Jim,

How would your model view the case in which the source transmitted
into the T-line for 1.5 seconds (delivering 150 joules into the line)
and was then disconnected, leaving both ends of the T-line
open-circuited.

In this case, you'd continue to have 150 joules of total energy stored
in the line (modulo the amount of energy which does manage to radiate
out sideways). However, there would be periods (of 500 milliseconds,
one per two seconds) when the voltage near the source end of the
T-line, and the amount of current flowing through the T-line in this
area, were both zero. For the intervening 1.5 seconds out of each 2
seconds, there would be strong current flow through this portion of
the line (having a standing-wave characteristic for all but a very
short transition time on either end).

This state of affairs can, I don't doubt, be modeled purely as a
matter of interaction and interference between fields. The model

would appear to me to have to become extremely complex, in order to produce the correct results at all points over the two-second long-term periodicy of this system.

It can also be modeled as the effect of interference between forward and reflected waves... and this is a somewhat simpler model to use to describe systems such as this which do not exhibit a purely steady-state behavior.

As far as I can see, *neither* of these models (fields, or reflected waves) is fundamentally superior to the other. They are both equally capable of producing an accurate description of the output of the system at any point in time, given a set of inputs to the system. Hence, by the usual standards of the validity of a scientific theory, both models are equally valid.

Under certain circumstances, one model may be more "practically useful" than the other. My impression is that your model of fields may be more useful in looking at relatively local behavior (e.g. within a wavelength or two) within a system that's at, or close to a steady state. Cecil's preferred model of reflected power may be more practical to use (i.e. simpler computations to produce a valid result) when dealing with systems far from steady state.

In between those two extremes, it looks to me as if which model one prefers is simply that - a personal preference.

You are, of course, talking about NET energy, and I agree with you about net energy. But it is easy to prove we are NOT dealing with net energy by observing
ghosting on a TV signal. It is easy to prove that multiple re-reflections are
indeed actually occurring in reality.

Your argument is that if 5000 cars cross the bridge into the city during the day
and 4990 cars cross the bridge out of the city during that day, that only 10 net cars have crossed the bridge in a day. I agree with your net figure but note that the bridge cannot be replaced with a 1 car ferry boat operating tens times per day which is akin to your above argument.

I'm glad you brought that up. Here is the EXCEL spread sheet for that same signal generator equipped with an auto-tuner. You are right in that it takes a longer time to achieve steady-state but everything becomes completely clear after 30 seconds and the results are exactly the same (using a 100 watt
signal generator).

3379. New program. Dipole+Line+Balun+Tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-30 23:58:58 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <SKednQ6g3qpAfeHZRVnytQ@bt.com>
Source record: 58622

New Program : LINELEN.exe

This program calculates dipole feedpoint impedance, transmission line
input impedance, and balun input impedance, versus frequency.

Dipole and line can be of any length. Line Zo can be of any
impedance.

Power lost in antenna and line is calculated. Also overall loss.

In addition to its educational value, this program will assist users
to change line length when the impedance presented to the tuner is
beyond its capability to transform it to a resistive 50 ohms.

Download self-contained program LINELEN, file size = 53 K-bytes, from
website below.

First, I would suggest you skip the DL6WU design. While it is good, the K1FO design has much better charactistics overall, better gain, better noise temperature, better pattern, better bandwidth.

And the answer, from a long series of 2m/70cm band interlaced optimizatations I did 15 years ago is, don't bother.

That being said, there is another way to do the dual band that does work. If you'd like to know, drop me an email, and I'll sewe if the guy who thought it up agrees to let me tell you. I did a bunch of modeling for him on the idea last year, and it should work.

To tantalize, it let you put 6, 2 and 432 on one boom. And they all work well with good bandwidth and pattern.

Any NLRS members reading (there's at least one) who were at Aurora 2005 know who came up with this neat idea.

Please note that your numbers and mine agree exactly.
Also please note that I posted those numbers days ago
on qrz.com under a brainteaser thread. I have the EXCEL
file if you or anyone else would like to have it. (In a
one second long transmission line, when the load reflects
50 watts, it has essentially reflected 50 joules because
nothing changes during the following second.)

In fact, I'll present a challenge for you and everyone
else. In any one second long lossless transmission line
with any forward power and any reflected power, I defy
you to come up with an example where the number of joules
stored in the line is not equal to the forward power plus
the reflected power. Those joules are the joules sourced
by the generator that have not made it to the load. The
conservation of energy principle will have it no other
way. The laws of physics win once again.

This does add the complexity of requiring multiple receivers, links,
sites and a voter to get even coverage, but if the equipment is
available, it works, or can work very well and you do not have the
ticklish process of setting up a series of band pass/band stop cans
which is usually three on transmit and three on receive.

I have forgotten the specific distance required for
separation/isolation, but it's considerable and I believe it's close
to a mile, maybe more. I'm sure some one on here can come up with the
specifics.

By definition, a "radial" would be physically orthogonal to the
other element. The elements in an OCF are usually collinear.

> LA4RT Jon

We don't seem to have widely used, descriptive
names for these configurations. Cecil is correct,
and perhaps the OCF referred to should be called
an OCF "L". The vertical radiator with a single,
elevated, horizontal, resonant "radial" perhaps
should be called an "L" dipole.

On inspection, either antenna, on a boat with a
tuner at the feedpoint, could be mistaken for the
other. You could tell the difference only by
observing how the antenna is operated. If the
antenna is operated only on those frequencies for
which the horizontal element is an odd multiple of
a 1/4 wavelength, we would call the antenna an "L"
dipole (or whatever).

If that same antenna were operated not only on
those frequencies, but on all others (HF spectrum)
as well, we would call it an OCF "L".

But if, on inspection, the antenna has multiple
resonant radials, that would unambiguously
differentiate it from the OCF.

Whenever the two antennas are physically
identical, they will obviously operate identically.

Make sense, Jon? Sorry for the confusion.

73,

Chuck

Hi Chuck,

Don't know how you got this miss-impression.

>2) Wire in water
>
>A one-foot length of wire immersed near water surface is sufficient for
>near-perfect results based on W7EL's NEC-4 model results. Assumed
>performance is similar to grounding plate.

This conclusion is conflict with the first, making it a mystery how
you came to either in summary. The focus on "water surface" is as
though you are trying to force it work like a pool of mercury. Water
is NOT a ground plane in the sense of conductivity. Water is a
terrible conductor. It is only its huge mismatch with air that gives
it such superb propagation, not match, characteristics. Distinguish
between the two.

>3) Radials
>
>Even shortened (loaded) radials elevated over seawater work as
>near-perfect based on N6LF's NEC-4 modeling. Objections to radials are

The objections are they are wholly unnecessary when ground is so
easily achieved by conventional means. You would need 120 radials to
shield against the loss you perceive, and that loss doesn't matter
when you stand to gain so much in propagation. You couldn't even
field a tenth of these radials. At HF, and maintaining their tune
and symmetry, you would be lucky to fit in 2. At that stage of the
game, there is absolutely no match advantage over conventional
techniques aboard a small craft (and at HF you don't qualify for any
thing other).

>4) Counterpoise (i.e., mast, forestay, shrouds, lifelines, engine, metal
>tanks, 100 square feet of copper, keel, rudder, etc. bonded together)
>
>This type of
>counterpoise is also the approach recommended by both Icom and SGC.

Only because it is already available and doesn't ask you to go any
further for no obvious advantage.

>5) OCF dipole w/horizontal component along deck
>
>Not commonly used,

Who would choose a complicated design over so many simple ones?

>Is that where it stands, folks?

If you want a dipole, make a VERTICAL dipole, even a lousy one.

Finally, and to repeat, learn the distinction between matching and
propagation. Your focus on matching issues is like seeing your glass
3/4ths empty. Looking at the propagation advantages in comparison is
like seeing a pitcher of water nearby that will fill that glass a
dozen times.

Richard, there you go again, overcomplicating quite simple matters
with your Shakespearian, Queen Elizabeth the 1st English.

Anything you toss into sea water makes a good ground.

You can consider the connecting lead to be a part of the ground sytem
or a part of the antenna. Take your pick. You will get precisely the
same answers, on analysis, whatever you do.

For the Wireman's ladderline # 551, where would I find the line loss
at 10 mhz in db per 100 feet (and why feet, when the other parameters
are in meters?)?

That domain is well named.

But, your 'needs' are off topic in this antenna ng.
I think you want to ask in rec.radio.cb.cretins.
It's the sort of thing they would use for their 'roger-beep'.

Hi Reg,

Thank you for making yet another of your projects available
to the group!

But I am curious: What program inputs are required to
calculate losses for tuners and baluns? Schematics? ;-)
Coil Q? Wire type and gauge? Loss factors for ferrites?
And how would one KNOW these parameters for real-world
examples, say a Palstar AT-1500DT versus an Ameritron
ATR-30?

Ed

Hello Richard,

Perhaps the context for the summary was unclear.
My objective was simply to identify several
existing recommendations for obtaining RF grounds
on plastic and wood vessels over saltwater.
Regrettably, I lack knowledge of any published
theoretical or empirical comparison of these
proposals that provides an objective, quantifiable
measure of performance.

> Don't know how you got this miss-impression.
>

That it will not work if submerged as much as four
feet? From Roy's report on his NEC-4 modeling. It
is presumably based on the known skin depth of RF
at 14 MHz.

>> 2) Wire in water
>>
>> A one-foot length of wire immersed near water surface is sufficient for

> between the two.
>

Well, some of what you are saying is pretty much
what I had thought. If you read my posts on the
other thread, you'll see where I was heading.

We agree that seawater's conductivity is lower
than copper's but greater than earth's. We agree
that a single ground rod driven into the earth
will perform poorly as the only return path for a
vertical antenna over land, but at least in some
cases will perform better than if it were not
there. Will a wire dipped into the sea perform
better than the ground rod driven into the earth?
I doubt there is much disagreement on that, even
though water might be characterized in relative
terms as a "terrible conductor". The only relevant
question, then, is "how much better?" and so far,
the only numerical answer that I am aware of has
come from NEC modeling.

The characterization I reported of a wire dipped
into the sea is based on Roy's modeling, assuming
I have not misunderstood of course. Others have
made the same point, but now we have model results
to support it.

BTW, I have just discovered a response from Roy to
one of my posts on the other thread that is
available on Google, but has never shown up on
either of the two newsgroup subscriptions I have.
Roy addressed some of my concerns in that post so
if you have not seen it you might do a search for
it on Google.

What loss is it that I perceive? N6LF's results
show near lossless results with only four
shortened radials over seawater.

> when you stand to gain so much in propagation. You couldn't even
> field a tenth of these radials. At HF, and maintaining their tune

Other studies have shown a single elevated radial
over land to lose less than one dB over a perfect
ground plane.

At that stage of the
> game, there is absolutely no match advantage over conventional

Well, what makes life interesting is that to
advocates of the other approaches, there are
obvious advantages.

>> 5) OCF dipole w/horizontal component along deck
>>
>> Not commonly used,
>
> Who would choose a complicated design over so many simple ones?
>

Multiple resonant radials that cover the popular
marine and ham bands on a small boat are not seen
by all as simple. One might ask the same question
of those who advocate the counterpoise approach,
since the wire in the water is simpler. I think
choosing the best system (broadly defined to also
consider operation over fresh water and
near-vertical radiation when important) will be
easy if we can only get some objective,
reproducible data and/or analysis.

>> Is that where it stands, folks?
>
> If you want a dipole, make a VERTICAL dipole, even a lousy one.
>

Certainly worthy of consideration. Many backstay
antennas are probably operated as half-wave
vertical dipoles (end-fed, of course) above 10 MHz
or so.

> Finally, and to repeat, learn the distinction between matching and
> propagation. Your focus on matching issues is like seeing your glass
> 3/4ths empty. Looking at the propagation advantages in comparison is
> like seeing a pitcher of water nearby that will fill that glass a
> dozen times.

I didn't address any matching issues at all that I
can see, Richard. Sorry if I misled you.

All of the alternatives utilize the same seawater
for propagation and the same vertical radiator.
They differ in whether there is any high-angle
radiation from a horizontal radiator, and possibly
in the magnitude of their "ground return losses."

Appreciate your comments.

> >>

I hope I did not cut incorrectly in the complex post...

The effect is that the *impedance* looking into each antenna will change due to the mutual coupling of the two antennas. You can also think of it as each antenna is not just staring into open space, but you can consider the field of the other antenna to be changing the space around the first antenna (and visa versa). It is also not umlike simply putting a reflecting plane or other paracitic elements neat a driven element - the feed point impedance changes. This power, being from the same transmitter, is coherent (phase locked) and therefore changes the current that flows which manifests itself as an impedance change. Given the current from the feed line voltage and then the superposition of the current induced from the other antenna, you get a new current that flows (aparently from the feed line voltage) and therefore it appears as a different impedance (from the feed line's perspective). I hope one of these analogies works for you.
This can indeed cause amplifiers to do funny things if they can't handle the resulting SWR. If you correctly match to the new impedances, there should be no problems, just the new antenna radiation pattern.

Side bar:
For some situations, the resistive part of this new impedance can even go negative. This means that this antenna is absorbing power, not radiating it. This can happen in phased, directive arrays used in broadcast. A friend of mine described such a situation that vexed him for a while until he improved his calculations to be more general to be applicable to this situation (to get the correct result).
Don't ask me how to match to a negative resistance. All I know is that given some certain directional pattern that is desired, this happens and with the proper math you can design a matching network that works and

restores order to the universe and keeps the big bang happy (:-)

3404. Origins of the Magnetron

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-31 21:42:49 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <463s72hn6rjebqshn3slpe6hk1hlo8ec08@4ax.com>
Source record: 58544

Hi All,

Just a bit of RF history obtained from "Forty Years of Radio Research," by George C. Southworth while I was doing some research for a correspondent:

"As early as 1921, Dr. A.W. Hull of the General Electric Company described the characteristics of a device which he called a magnetron. It consisted of an axial filament surrounded by a cylindrical plate between which a constant radial electric field could be impressed. Superimposed on this arrangement and at right angles to the electric field was an axial magnetic field.

... "Later the inductive load was reduced to a tiny Lecher frame. A magnetron with this configuration was placed inside a small waveguide by Dr. Harold S. Howe of the University of Michigan to obtain a top frequency of nearly 50,000 mc. (1938).

"A few years earlier, 1934, Dr. Cleeton and Professor Williams also of the University of Michigan had ... discovered a pronounced absorption band for ammonia at about 27,300 mc. This ultimately led to a new time-keeping device of high accuracy.

... "Finally the plate was made from a single block of copper with appropriate segments milled inside its hollow periphery, each representing an individual oscillator. This important step was taken by physicists at the University of Birmingham in the late thirties. They also applied plate power in short pulses and at much higher levels than had been used previously. This was not only more appropriate for good magnetron operation but it provided an almost ideal signal for radar use. ... Details of this device were brought to America first by Sir Robert Watson-Watt and Drs. Cockcroft and Bowen in September, 1940."

I think most of this, and a whole lot more concerning where the development of the cavity magnetron lead, is in Robert Buderi's book, "The Invention That Changed the World." Potentially very interesting stuff for any techie.

In the last paragraph you quoted, there is what I consider a mistake that can lead to misunderstanding of how things work. It suggests that each cavity is an oscillator. The cavities are no more oscillators than a bottle. Each is a resonator, whose resonance is excited by the stream of electrons flying past, in much the same way as the bottle is a Helmholz resonator which is excited by the stream of air flowing past. In each case, what's going on in the resonator affects the stream flowing by in a way that lets it further excite the resonator synchronously with the resonant energy that's already there.

Cheers,
Tom

Hi Chuck,

You are drawing conclusions from different facts. These plates are successfully put to this very purpose every day. There is no model that says that a dynaplate submerged 4 feet "will not work." The object lesson is that it will merely be a tie point to the length of wire that is working every inch to it, and that the current in the last inch will, in all likelihood, not see any benefit of that plate, IF AND ONLY IF that wire travels through the water, or in very close proximity to the water. The plate is not ineffective, it is merely redundant.

If the wire travels through the interior of the boat, where most transmitters reside, that dynaplate will conduct just as well, and at as high a current as is necessary for a modestly efficient connection. This is, after all, the whole point of installing these plates.

Other's have commented you can as easily wire to the engine (if you have one) to create one great big gobstopper of a capacitor to the water. Capacitors work quite effectively too, they are called counterpoises. No engine? The same surface area in metal will substitute. Too much surface area to equal effectively? Move the capacitor plate closer to the hull, and reduce the area by proportion. Does it matter your hull is fiberglass? None whatever.

>What loss is it that I perceive? N6LF's results
>show near lossless results with only four
>shortened radials over seawater.

You still don't know how much loss there is through conventional means, then, do you? "Near" lossless is not quantitative data.

>Other studies have shown a single elevated radial
>over land to lose less than one dB over a perfect
>ground plane.

You have terrible sources for "other studies," then. That elevated radial must be up a wavelength. How does this relate to "RF grounding methods for sailboats?"

>Well, what makes life interesting is that to
>advocates of the other approaches, there are
>obvious advantages.

You still don't have anything that amounts to more than testimonials.

>Multiple resonant radials that cover the popular
>marine and ham bands on a small boat are not seen

>vertical dipoles (end-fed, of course)

Then it ceases to be a dipole.

>I didn't address any matching issues at all that I
>can see, Richard. Sorry if I misled you.

Every comment of yours that contains counterpoise, radial, loss, skin depth, length of wire, or connection is a matching issue.

>All of the alternatives utilize the same seawater
>for propagation and the same vertical radiator.
>They differ in whether there is any high-angle
>radiation from a horizontal radiator, and possibly
>in the magnitude of their "ground return losses."

If they all utilize the same seawater for propagation and the same vertical radiator, they all suffer equally - it stands to reason there is no difference given all the "sameness." It also stands to reason by your assertion that they differ, that they do not all use the same seawater or vertical.... Which is it? Let's skip that and cut to the heart of the matter. How MUCH different?

Start with a conventional untuned vertical using a dynaplate and tell me, in dB, how much better any other scheme is. Let's confine this to a practical situation where the rig is under cover and inside the boat and that you need two leads, one from the tuner antenna connection, and another from the tuner ground connection.

Ed,

I've just spent half an hour thinking about how to answer your question without having to write books on the various subjects.

What sort of gadgets are a Palstar AT-1500AT and an Ameritron ATR-30? Who are Palstar and Ameritron anyway?

Manufacturers might know. Have you tried Google?

Hi Tom,

I defer to the author's explanation, and the nature of writing for a wide audience. This group would be such an example.

The author mentions, in portions not quoted, that the electron beam/current/what-have-you streams at a grazing angle along the arc of the inside of the plate, crossing these openings. The cavities are, then, parallel plate loads.

It stands to reason, on the other hand, that there is only one output from ostensibly one cavity whose fields are sharing the passing stream of electrons that is also resonating. In fact, this operation (also described by the author) led to understanding and development of the Klystron tube and other traveling wave amplifiers.

Not to much to study...Find a good place for the radio.
Mount it. Throw the antenna on the car, and run the
coax through the best opening you can find. The only
real important thing to consider is the power source.
Don't !!! use cig lighter plugs, etc. Run fairly thick
wire directly to the battery, and fuse both the + and -
wires. If you do that, you may have to find a plug or
hole in the firewall. Most have a rubber plug of some
type. If not, you might have to drill a hole.
But at least you won't have problems with the rig
from big voltage drops due to too thin a wire, or
crusty corroded cig lighter connections/socket.

> are in meters?)?

==========
Bob,

If you don't know the attenuation of your transmission line you shouldn't be using it.

A standard method of defining the vital attenuation parameter of a transmission lines is "Decibels per 100 feet at some frequency or other." It is probably stated in that form in bibles such as ARRL publications.

And a reputable American manufacturer will probably state it in his sales catalogue. Or he ought to.

Frequency is mentioned because knowing the attenuation at one frequency allows it to be accurately calculated at any other frequency. As is done thousands ot times in the program.

The program asks for dB per 100 feet because, out of consideration for USA citizens, the foot is the unit of length with which they are most familiar. And for the rest of the World there is a statement in the program notes that "100 feet = 30 metres."

The alternative to asking for dB per 100 feet at 10 MHz is to provide a look-up table which lists by name the attenuation of hundreds of different types of transmission line used in the USA and the rest of the World.

Or the program could ask for conductor diameters and conductor spacing in the case of twin lines, inner and outer diameters for coaxial lines, also the dimensions and electrical properties of the insulating materials. And then calculate attenuation versus frequency.

A large number of numerical program input items would detract from a program's usefulness. Users would soon get fed up with using it. And the programmer would get tired of writing any more.

Attenuation and Zo are the most important parameters of a transmission line. To keep things simple for both program users AND the programmer it is best that both parameters be entered directly.

Try Google.

The main purpose of the program is to calculate the impedance
presented to the tuner. For accuracy, line loss must be taken into
account.

Large wires, Anderson plugs are good ideas.
I have a question, though. If you're running, say 10 to 15 watts to a
automatic screwdriver HF antenna, can you get by with cig lighter
connection?

Thanks,

John

My GMC pickup has two auxiliary connections in addition to the
cigarette lighter. My IC-706 runs 100W SSB just fine off of one
of those aux connections. But pickups may have bigger wires than
cars.

It is still recommended that you use direct dedicated wiring to power
your radio. You may be at 15 watts to day, tomorrow who knows.

Richard,

Randall & Boot's original magnetron used to be displayed in the London, England, Science Museum. It was all by itself in a very large, securely locked glass case. No magnet. I don't know whether it is still there.

It lay there, all forlorn, hardly noticed, about the same insignificant size as a small, half-size, rusty can of baked beans.

My sentiments lie with R and B, slaving away in the laboratory at Birmingham University while the Luftwaffer rained down bombs and incendiaries on the city. At the time, the top-secret goings-on were unknown to me, and I spent my time in a corrugated-iron air raid shelter in the back garden just a few miles down the road.

A few years later, having joined the RAF as a Radar technician, I had the pleasure of holding a production model in one hand and the magnet in the other. At the other end of the workshop bench a parabolic dish rotated once every two seconds. It is not true that a 50 kW peak pulse power at 3000 Mhz sterilises one's reproductive organs. I have fathered 5 children.

It was left to the Japanese to populate the World's kitchens with microwave ovens. Beyond the first, no magnetron has ever been made in the industrial city of Birmingham, England. But they don't make many motor cars there any more either.

Reg,

Perhaps I assumed too much about amateur radio being a global
market.

Palstar is the brand name of a popular line of high-end antenna
tuners (aka transmatches) that are made in the U.S.A. Ameritron
is best known for their broad line of H.F. power amplifiers, but
they also make a couple of antenna tuners; the ATR-30 is one.
(They are now a division of MFJ; and it would be amazing if
you haven't heard of MFJ.)

Feel free to substitute antenna tuner models that are more familiar
to you into my question, if that will make it easier to understand.
I'll also try restating the question:

What parameters does a user input into your newly-posted program
in order to estimate tuner and/or balun losses?

Predicting such losses seems inherently difficult to me; and even if the program could handle all the necessary parameters, I have a hard time seeing how one could obtain the necessary values to characterize typical commercial (or homebrew) tuners and/or baluns.

Re Google, doing a search on "Palstar" leads one straight to their products, including the AT-1500 series:
http://www.palstar.com/at1500cv.php
Similarly, doing a Google search on Ameritron leads one straight to their products, including the ATR-30:
http://www.ameritron.com/products.php?prodid=ATR-30

But I am sure that neither manufacturer has posted parameter values to use in your program--despite your well-deserved notoriety in this NG. So I am quite sure that Googling for those would be unproductive.

The Japanese proved adept at improving and producing high quality technical products. Japanese didn`t market the first microwave oven. Raytheon introduced its "Radar Range" soon after WW-2 ended. Japanese copies were innovative, reliable, and cheap, so they won instant acceptance worldwide.

The magnetron has been called the best import ever from Britain and I think that comparison even included Bob Hope and Liz Taylor. At the time of the magnetron gift to the U.S., British war production was already bursting at the seams and the U.S. was well advanced in radar and had a few tricks up its sleeve to improve the British gear.
I`ve noticed early British airborne radar using yagi antennas. That seemed quaint to me.

Best regards, Richard Harrison, KB5WZI

All the major powers were well advanced in radar at the time. All the ideas were already in place, and engineers everywhere were starting to put them together. However, as Reg points out, freedom from bombing raids is a wonderful aid to creativity.

The USA developed ways to mass-produce the magnetron, notably a method of building up the cavity from laminations rather than needing to have a skilled machinist mill it out from solid (and before Roy gets a word in, they fixed the oil leaks too).

>I`ve noticed early British airborne radar using yagi antennas. That
>seemed quaint to me.

Those were the phased arrays for the earlier VHF radar, and consisted of two or four two-element yagis clustered around the nose (of a two-engined aircraft, obviously). This gave a fairly good forward-looking capability. Both sides did much the same, and given the relatively long wavelength, it's hard to think how better to do it.

The huge benefit of the magnetron was that it operated at much shorter wavelengths, which frees up the antenna design and provides much better spatial resolution - witness the downward-looking "H2S" radar which was the magnetron's first major deployment.

"Old Ed" asked -
>
> What parameters does a user input into your newly-posted program
> in order to estimate tuner and/or balun losses?
>
==========
Ed,

Program LINELEN's primary purpose is to calculate the impedance presented to a tuner. It will assist the user to change the length of the transmission line, hopefully to bring the impedance into a range of values which can be better handled by a tuner.

The program cannot predict tuner losses. It has not been designed to so.

You are asking what input data would be required if I wrote another program which included calculation of losses in a tuner.

There is already a program named T_TUNER which designs a common or garden T-tuner and also estimates its losses. In practice, nearly every manufacturer uses the same basic circuit which consists of two variable capacitors, each of about 350 pF maximum, 30 pF minimum, and a coil which may be tapped to change bands or it may be a variable roller-coaster.

For a different tuner circuit another program is needed. There are L_TUNER, Pi_L_NET, PI_TANK. And DIPOLE3 which deals with antenna + balanced line + balun + coax + Tuner Design.

Download program T_TUNER and read the informative introductory notes.

Input data includes maximum capacitor settings. The program automatically prevents maximum capacitor settings from being exceeded. This is a form of technical information which restricts practical operation. Minimum component settings are not called for. But the program user must keep in mind, when calculated capacitor settings are less than the actual value with capacitor vanes completely unmeshed, the tuner won't work.

The program asks for capacitor Q and coil Q. The progam user will have to take the tuner out of its case and inspect construction and then make use of his experience and judgement. It will not be worthwhile taking the thing apart to measure component Q. Q is needed to estimate component losses for a given transmitter power. The program gives advice about estimation of Q values.

When a program includes design of a coil, length, diameter, wire gauge, etc., its Q is always calculated. Whether the power loss is calculated depends on program application.

The program user will also have to estimate maximum working volts of the capacitors although this is not a program input. But the program does calculate and display actual capacitor volts for a given transmitter power.

Equipment power related performance parameters are nearly always estimates. T_TUNER has built-in estimates. There is no point in calculating to a greater accuracy than contained in the user's input data. Very often crude estimates are good enough. As the programmer I reserve the right to decide just how crude. And you can't argue with me. You can always have your money back. ;o)

The same applies, for example, to estimates of radiated RF power for a given transmitter output power when there are losses in the SWR meter, the tuner, the balun, transmission line, antenna, and the ground.

It is only necessary for a program user to realise that he, himself, invariably makes estimates.

Most amateurs and many professional enginers suffer from delusions of accuracy, often proudly naming their measuring instruments.

Reg, G4FGQ.

I would also add that sea waters conductivity is not a consistent as
some seem to think. The salinity of salt water varies with temperature.
NASA has surveyed most of the world oceans using microwave radar and
salinity if far from consistent. This fact combined with tidal flows,
man made pollution from storm water drains and other factors makes
"connecting" to sea water seem dubious.

If we assume you can connect to sea water, do you want to place most of
your current in such a small area? I doubt someone could keep this
connection clean enough in seawater to be efficient. This fact combined
with electrolysis will lay waste to any connection very quickly. Maybe a
gold plated conductor might be able to survive in a salt water environment.

The way most people install radials in yacht would make them elevated,
rather than buried below skin depth. N6LF has indicated in his modeling
that short radials as long as .1 wavelength work just as effectively as
0.5 wavelength radials over sea water. Since you not trying to combat
ground loss whats the point of trying to build a radial field when 2 or
4 .1 wavelength radials will do the job? Besides building a elevated
radial system will have some capacitance to ground. A single radial
should over sea water capture most of not all of the antenna return
currents

Besides from all the posts i have read burying something like a
Dynaplate below skin depths is akin to burying your rf current below a
copper plate. I also believe there is a rule of thumb that 5 skins
depths is the maximum return on investment in using the available
conductive depth of any material. Its probably that its only ever the
piece of wire to the dynaplate thats working as a short radial. I dont
see how anyone can say a dynaplate could ever work when below skin depth?

One thing i am curious about is that if you suspend a radiator or
conductor well below skin depth in air whats the radiation efficiency

like of that conductor? To me on a yacht it looks like a conductor suspended in a U channel suspended in air with the top open and exposed. Maybe it will operate like a waveguide with some cut off frequency, this is a wild guess.Maybe someone who can model conductors below ground can model this. Most yachts have at least 3ft of freeboard above water to play with.

But who knows there seems to conflicting advice on several points. Maybe Roy can clarify all these issues with his models.

Many years ago, I used a 35 watt transceiver on a cigarette lighter plug. Someone told me I was making a mistake. We measured the output of the rig, connected it direct and measured it again. The output of the rig was a few watts lower on the plug as opposed to direct wiring. It wasn't significant enough to be detected on the air, but it proved the inefficiency of using the cigarette lighter for a source of power. I now use #8 wire directly to the battery for all my mobile amateur radio wiring.

I never tried to determine if it was the plug itself, or the wiring that caused the power drop, but I found a website that allows you to calculate the voltage drop of wire given the length, wire size and current.

Well years back there were CB STORES everywhere, and places like Sears
and Wards sold CB's, not anymore. Someone has to sell them.
Very litle interest in CB these days, however its the only real way to try and communicate
with other drivers on the road.

Negative feedpoint resistances in phased arrays have of course been known for a very long time. One of the example files (4Square.EZ) which comes with EZNEC shows an element with a slightly negative feedpoint resistance. The accompanying "antenna notes" file includes a brief explanation of the phenomenon.

You can't "match to" a negative resistance, because matching requirements are determined by the load, not source, impedance, and an element with a negative resistance is a source rather than a load. But there's no necessity to match individual elements and, in fact, attempting to do so complicates the problem of achieving the desired element current ratios. One thing you can count on, though -- the resistance of the whole array will be positive. And that's what needs matching.

Hi Steve,

That makes sense (and subject for scientwists to argue "it can't be" :-)

I was considering two scenarios for contesting.
One, mainly for expeditioning case, use two smaller amps (transportation
limitations) and low power (continuous) phasing network between the exciter
and two amps feeding two antennas.
Two, feeding two amps and two antenna systems firing in different directions
(offset stacks).
I tried the crude application of it, and was "bugged" that my CW tone or SSB
modulation was raspy. I knew that rig was OK, firing one leg was no problem
and had to conclude that the problem had to be mutual coupling, feedback and
"beating" back in the amp circuits. I did not pursue the rectification of
the problem, considered it too complicated for what I wanted to do. Learned
it to be a no-no trying to feed phased arrays with individual amplifiers, at
the same frequency.
Feeding antennas that are widely separated with no mutual coupling, firing
in different directions, should not be a problem, as long as there is no
significant signal being induced into the other system.
We will play with some outrageous combinations of about 40 rhombics and
other antennas, capable of being fed by 16 transmitters from the new Tesla
RC QTH of old AT&T Ocean Gate NJ site (makes old W6AM site look like
kindergarten :-). Antenna matrix (wall unit) switch that does the selection
is a piece of art in itself. We have to get rid of pigeons and "paintings"
they left and get the site operational by the fall contest season.

> so.
>
Reg,

Thanks for the clarification.

I might note that it's easy to see where I got the idea that LINELEN
attempts to calculate tuner loss. Your first post in this thread had
the subject line "New program. Dipole +Line+Balun+Tuner"; and
it included the line "Power lost in antenna and line is calculated.
Also overall loss." In order to predict *overall loss* of the chain
described, balun and/or tuner loss would have to be included.

From the balance of your remarks, I conclude that you (like me)
don't think that accurately predicting the losses of real-world
tuners is a very practical undertaking. (Sometimes empirical
measurements rule.)

I hope many find your program useful for what it IS designed to do,
and thank you again for making it available.

"Anything you toss into the sea water makes a good ground."

Certainly correct if "anything" is a low-impedance RF path.

If "skin effect" prevents penetration to a copper plate on the hull,
fine. RF has then made the transfer to the sea at a shallow depth.
That`s the goal.

35 years experience tells me that biggest issue regarding voltage drop in most wiring harnesses is the connections, not the wire itself. Unsoldered metal to metal connections, especially crimp type, are especially problematic.

I`m not sure separate amplifiers have anything to do with distortion because I`ve seen distortion at certain azimuths from arrays driven by a single amplifier.

Drive around a broadcast array with sharp nulls while listening. You will notice severe distortion at the edges of sharp nulls. I always attributed this to phase out of the carrier frequency at an azumuth where the sidebands aren`t completely nulled out, and this produces the overmodulation and distortion. It`s only a speculation to explain the cause of an observed effect.

Roy,
I didn't mean to imply it wasn't known previously, only wanted to give a real life example (as a preemptive attempt at heading off a potential "but that's all theory" response -- perhaps a little gun-shy on this news group (:-)). I also have no direct knowledge of this type of the network design, but it has to be designed and the antenna with the neg real part is part of the system that gets hooked to the network.

> You can't "match to" a negative resistance, because matching

OOPS ! I *know* what you mean, but it takes knowledte of both ends - We, me included, can eaily forget that we have an arbitrarily defined (50 ohm) system that we easily take for granted. ya gotta know you're in a 50 ohm (or whatever) system to "do" the match.

No. I have successfully blotted all that stuff out of my mind, but,
then, I was a short-timer from day one. Perhaps I do remember something
like CNCPACFLT (sync - pack - fleet)...

I was in the Phillipines, uh oh! it's comming back ... NAV COM STA PHIL

> I/we demonstrated with two links of chain, connected back-to back to make
a

Totally cool demo. I first became aware of it when I had litterally a
garage repair shop, after the Navy. I had a Motorola monitor receiver that
sat on one common frequency and was used to measure deviation on 2M radios
in the late 60's/70's. If I keyed a transmitter on another frequency and
happened to scrape a screwdriver on another condusting surface, I'd hear
noise in the monitor. I therefore dubbed it the "screwdriver effect".
Later, at Motorola, I had to track down some receiver desense in a car phone
and traced it to pickup of the Caddy trunk-closing motor wiring, somehow
bringing RF into what appeared to be the dash and possibly a lousy
oscillator for some unknown equipment, that, was re-radiated causing Rx
noise. I also had to look for some "motion induced desense" and found

bumber mounts and also motorcycle seat springs to be responsible. I had to develop a detection system and used one of the FM receivers with a weak, slightly off ferquency signal injected in parallel with a small loop to sniff the offending junctions while someone bounsed on the suspect body part ... At that time, that's when I ran across rthe paper describing the HF interference via the deck chains to the radars on NASA ships. We dubbed this effect "Environmental Desense". There is a 2M repearer in NE Illinois that has this quite often when there is wind.

Source record: 58481

Dave has some good info too, but here's some background.

Transmitters ALL have noise coming out that decreases as you move away from the carrier. We call this sideband noise. This noise can cover up your received signal if it is high enough (which is not difficult) on the receive frequency. A duplexer or cavity set can (if needed) have a notch at the _RX_ frequency to reduce this noise. Cavities like this are called "pass-reject" cavities because they have a band-pass characteristic for the transmitter frequency and a notch which can also be tuned to the receiver frequency to reduce this noise more than the simple cavity skirts can.

Transmitters can have spurs and if you have that, you have a similar problem because it is just a single frequency which could cover a received signal and you must reduce. However, chances of having a spur on your receiver frequency is rare (though synthesizers can cause quite a few near the carrier, so you want to stay away from a synthesized radio if possible, for a repeater, for that reason)

While we talk of "receiver overload, blocking, desense" receivers have one characteristic which is not obvious to most. Since ALL oscillators have this sideband noise mentioned above, the local oscillator IN the receiver also has some. When a strong carrier enters the receiver (your own transmitter), _it_ becomes another local oscillator in the mixer and can mix with the sideband noise of the intentional LO. This mixes some part of the sideband noise of the LO onto the desired frequency. This is one of the mechanisims for receiver desense and one reason to reduce the amount of TX power getting to the receiver. With synthesixed receivers, it CAN be the dominant cause for desense. This is because the VCOs needed for synthesizers typically can have quite high sideband noise. Since a typical radio is not designed for repeater operation, it's design will not try to optimize for sideband noise.

On 2M you can probably hear this effect with just about any two 2M ham rigs. Talk to someone on the local repeater, but not too close to the repeater (I'd say at least 5 miles away) and drive close to each other. At some point he repeater will get noisy and if you have a good ear, you can hear that this noise is different than the normal, weak signal noise. When the other station de-keys, the repeater will quiet with it's normal gusto.

Glenn,
boy! I can't read all these posts, so I was trying to see where you were
going and asking by just skimming, primarily your posts.

The above caught my eye. Doppler is not "generating new frequencies" as a
non linearity does. A non-linear system will produce harmonics with one
exitation frequency and produce the common mixing / IM with multiple
exitation (superimposed) frequencies. I think trying to mix relativistic
effects in with the stationary world is an unnecessary complication of a
linearity discussion.
If I have time I'll try to follow the thread to see what you're really
after...but. If it takes mega watts to see some non linearity in an
antenna, who cares? and more importantly how will you know whree it is
occuring since things like the junction of two connectorc can produce enough
IM to mask other, smaller sources. If you tried an experiment looking
for IM / Mixing you might try to use a receiver becaue a receiver could be a
very sensitive detector...but you'd have to have a pretty good receiver.
Something like a kW LO and mixer to have a really good intercept.
I'm not sure of the point here... Do antennas cause IM?
Sounds like a deadend arena to me.

> 73's
> Richard Clark, KB7QHC

This is exactly right. If they all use the same water for RF Ground,
and vertical, for the antenna, then the only difference is, "How much
coupling from the ground stud on the antenna tuner does each system give
to the water?" And that is the Thousdan Dollar question. DynaPlate,
Bonded RF Ground System, wires, radials, whatever, all, just make up one
side of the capacitor, with the water as the otherside and the distance
between is the dielectric. More effective coupling equals lower
impedance RF Ground. All this talk of Modelling is just so much FuFurrR,
for anyone who has installed MF/HF Marine Antenna Systems on these type,
wood or plastic vessels. Anyone with much experience in the field will
tell you, simply, get as much surface area as possible, bonded with
low impedance connections, (Copper Strap) and get it as close to the
water as possible. The Physics of building a bigger capacitor is:
Have as much surface area as possible, with the least space between the
plates. This isn't Rocket Science, it is just basic physics, and all the
crap about tuned counterpoises, and copper screens in the overhead, and
the like is just that..... crap...woun't work, never has, and never
will.
It doesn't take a NEC Modelling Software Package to figure this out, it
just takes some common sense and a bit of OJT Experience....

Bullshit, where do you guys come up with this stuff....Skin Effect is a
a Boundry Thing, and the hull of the vessel is the "Boundry of the Sea
Water" even if it is 10 feet below the sea surface.

I wonder if we can really define that as distortion. It's distortion to you at the time perhaps, since the whole signal as you'd like it to be delivered is not there while you drive through the null. However, the antenna system is just doing its job, and doing it well in the directions it was intended. The nulls are by nature not supposed to contain signals with smooth frequency response, since they aren't supposed to contain any signal at all if perfect, correct?

Finally someone gets it! This is what Roy said way back in his first
report of his modeling, that the ground plate if fastened to the hull
will be on the surface of the water even if it happens to be several
feet below. The other side of the ground plate is air. In other words
the hull is displacing the water. Unless of course the boat has sunk.

For the guys that are referencing the N6?? Article about very short
elevated radials over sea water; please note that he is saying those
short elevated radials are tuned with loading coils.
Elevated radials will not work unless they are 1/4 wave resonant or
tuned with a loading coil.

That may well be. However, I still use the wire with the least
voltage drop I can reasonably afford. (#8 was available, flexible, and
relatively inexpensive for the length I needed, #00 was too stiff and
large to manipulate in my car. :)

The effect, distortion, seemed to be noticeable in any or all directions and over DX path. The only thing we could figure out, was that it had to do with separate amps feeding separate ants. Switching to either one, signals were clean. Feeding two antennas from one exciter through hybrid was no problem. In my case it was 4 square and Inv Vee about 3/8 wave away.
I have heard the same effect on one YU station, and he was getting reports of raspy signal and when I told him to turn the other amp off, he was clean. The distortion was quite significant, it produced complaints from about one in five stations worked. Closest thing to describe it, would like signals distorted by Aurora.

The VHF radars were still around into the late 1970's, maybe beyond. The US Navy had them on carriers for air search. I think the nomenclature was AN/SPS-29 and/or AN/SPS-37. The one I recall was in the 218 - 220 MHz and it was hell on TV channel 13! The antenna was referred to as a bedspring array; the rectangular framework for the dipole radiating elements resembled a giant bedspring.

Sure, but none of those would fly very well. The discussion was really
about airborne radar, where there are tough limits on antenna size.

Back in the early 70's I got a pair of magetron magnets that came out of old airborne radio set - can't remember the nomenclature - that the USAF converted into a weather radio. They were quite large and strong, and 'U' shaped. Someone swiped them in a move. Anybody know where I might find a set? Google and eBay haven't turned up anything.

It is interesting to speculate about the
proportion of displacement currents passing
through the air to the inside of the hull and then
through the hull to the grounding plate, vs. the
proportion passing from the surface along the
water-hull interface to the Dynaplate.

As Roy pointed out, one reason seawater "works"
despite its low conductivity relative to copper is
that a high percentage of the "ground" return
current is concentrated very close to the antenna
where path conductance is high. If the water path
from the surface to the Dynaplate is vertical
(four feet) does that mean return currents must
pass through four additional feet of seawater and
thus will encounter greater losses than if the
Dynaplate were at the surface?

Or will the vertical water path "collect" the same
or even greater return currents than a horizontal
water path? I've heard of radials sloping up and
away from the antenna at 45 degrees, but 90
degrees? (Assumes tuner ground terminal directly
adjacent to Dynaplate on other side of hull) Ought
to be easy to model.

Interesting, no?

>

Yes. That is what he reported on his modeling.

Elevated radials will not work unless they are 1/4
wave resonant or
> tuned with a loading coil.

This is not at all obvious to me except at a
semantic level. And lest anyone misunderstand,
Gary is not suggesting that N6LF made that statement.

Is an automobile body (on land) conceptually
analogous to non-resonant, elevated radials? Does
it work? Would it work less well over seawater
(let it levitate or make very quick QSOs)?

Would a random length whip on HF work with a tuner
and a single, non-resonant wire about 25 feet
long, in lieu of the auto body? Would it work less
well over seawater?

If you're with me this far, the next question is
"how much better or worse?". And then on to the
other tradeoffs: radiation patterns, safety,
simplicity, RF coupling, etc.

Alternatively, we can explore why it won't work.

Thanks, Steve,

Good post. You do need to read a little more: by mentioning Doppler shifts, I was illustrating that a linear system can generate new frequencies without violating the law of superposition. No relativistic effects needed here: a two-tone train whistle will not distort in the superposition sense under Doppler shift, but it can generate new (or different) frequencies. My point was that generation of new frequencies is not necessarily a valid test for nonlinearity.

My position on antennas is the same as yours. Earlier posts were confusing as the term 'linearity' was being applied to antennas in two ways. One in the electrical superposition sense (by me) and the other in current distribution along the antenna element. Electrically, antennas are very linear (I believe) even when their current distribution along the element length is not.

I stopped posting when I realized we were discussing two different things.

OOPS!

"pass through" should be changed to "travel along"
and the parenthetical expression (at the
hull-water interface) should be added for
clarification. Text above has been so edited.

Sorry about that.

Chuck

Chuck wrote:
"If thee water parh from the surface to the Dynaplate is vertical (four feet) does that mean return currents must pass through four additional feet of seawater and thus encounter greater losses than if the Dynaplate were at the surface?"

Well, the Dynaplate is at the surface of the water in contact with the hull. That surface makes a turn to the horizontal at the sea surface.

The Dynaplate could also be connected by copper strap(s) on the extertior of the insulated hull so as to contact the sea at a shallower depth depending on the list (tilt) and trim of the boat. Capacitive coupling through an insulated hull is usually comparatively easy at RF.

Radio appears to be circa 1980s Icom design

The IC-V200T Owner's manual (VHF-FM Transceiver)
http://www.icom.co.jp/manual/external/transceivers/IC-V200T.pdf

Of course, this Land Mobile Radio is designed to be pre-programmed
by an Icom Service Center.

Here is a web site concerning modifications and programming of the IC-V200T
by F5JTZ
http://f5jtz.club.fr/pjacquet/default.htm

IW3GPE Italian web page - some of the same materials as F5JTZ
http://www.negrello.com/icv200t.htm

This radio is programmed through the 10 pin front microphone connector.
A TTL-to-RS232 interface will need to be built. F5JTZ has a design on his
web page (using 2 opto-isolators).
A number of these designs exist on the Internet.

The Software CLONE17 (French software) only functions with the V200T
versions that have EPROMS of the "Pro origin", namely V8, V9 and V10 ....
but not with the SuperH16.

Hehhhhhh :)

That little ball is a magnet. It's what actually attracts and catches
those snippets of radio wave that are hovering all around you.

See? That's why coat-hangers never work as antennas.

;)

And supposedly aluminium can be used to amplify certain wavelengths.
Which is why tin-foil wads on the ionosphere also improve reception.

There's no good way to model this situation with the tools I have. Conceptually, though, you can get a fair idea by imagining the sea to be made of metal. The boat makes a depression in the surface, and you can connect to the metal at the bottom of the depression just as you can anywhere else on its surface.

Imagine that the depression is perfectly round and symmetrical, with a grounded vertical extending up from its center. The current flowing into the "ground" connection at the bottom of the depression will flow along the conductor's surface, up the sides of the "dish" to the flat water surface. The total current flowing from the center of the dish upward to the flat surface will equal the current flowing up the vertical wire near its base. The fields from the two will nearly cancel, so there'll be little radiation from the vertical in the region below the flat surface of the water. The vertical above that point should radiate normally. This simplification will of course be modified by the reality of a non-symmetrical hull, but it helps in getting a general idea of what will happen.

Another way to look at the situation is to view the depression as the outer conductor of a shorted coaxial cable, with the "ground wire" extending down to its center as its center conductor, and the shorted end the bottom of the depression. This shows you'd get some inductive reactance in your connection to the surface of the water. A rough calculation would probably get you in the ballpark of the actual value. This doesn't represent loss, however.

The main thing, though, is that connection to the water requires a conductor either in contact with or capacitively coupled to the water's surface or only a very short distance below it (assuming salt water), whether the surface is below the boat's hull in a depression or on the

flat surface of the ocean.

In a linear system, there only needs to be a straight line function between the input and output. The actual signals on the input wouldn't be very useful if only straight line functions were allowed on that input. The current distribution along an antenna element length only ever approximates a straight line. The only requirement for that current to obey the rules for a linear system is that it be a linear function of the source current and it is at every point.

Chuck wrote:
"If the water path from the surface of the Dynaplate is vertical (four feet) does that mean return currents must travel along four additional feet of seawater (at the hull-water interface)---?

Maybe, but there is a lot of area in that path. The hull-water interface includes the entire submerged surface of the hull. It has been assumed in this thread that the sail-boat hull is fiberglass, an insulator. The impedance of fiberglass is vastly different from that of seawater.

The great mismatch between fiberglass and seawater means a radio wave traveling along one of the surfaces won`t be readily absorbed into the other.

Dynaplate is a name given copperfoil on a roll. Dynaplate is also a name given a copper plate which has been etched to increase surface area thereby increasing its contact area with water.

The surface of seawater contacting a boat hull is continuous with the horizontal surface of the sea.

Vertical polarization is effective over seawater. Horizontal polarization is ineffective. The sea short-circuits the voltage wave.

A horizontal wire can produce vertically polarized radiation. The Beverage antenna works over poor soil. On page 720 of Kraus` 3rd edition of "Antennas" is the "Flush Disc" antenna which produces vertically polarized radiation over a highly conductive surface. It`s a radiator in a pit and should be useful in a vessel.

What are you building? Just experimenting?

I doubt there's a turn-key solution especially for 6m. There are some companies that sell four-square boxes for the low bands, but they're pretty pricey, and you're not going to get one for 6m.

I think the only plug and play phased array turner for 6m you're going to find is an antenna rotator to turn your yagi :-)

Transmitting array steering is a bit more difficult than receiving array steering. You can make RX array elements lossy enough to avoid trouble with mutual coupling and you can get closer to doing arbitrary phase combinations of elements, because you can do it with active components. With a transmitting array in amateur use, you need to use passive tuned networks, transmission lines, etc and it's harder to get "weird" (non-90 or 180 degree phasing).

You might be able to put together an RX phaser... I don't know if the MFJ 1025/1026 phase boxes go up to 6m but they might work for you for RX.

Let us know what you're making. I'm curious!

For single band operation, a simple decoupling stub or sleeve will
probably work. This is discussed in the ARRL Antenna Book.

For the RG58, each Steward HFB143064-300 (sorry for the ridiculous
link length):
http://www.steward.com/web_part_no.asp?line=EMC%20/%20EMI%20Board%20Level%20and%20Cable%20Core%20Products&family=Ferrite%20Cores%20for%20Cables%20-%20%20Wiring%20Harnesses%20-%20Connectors&product=High%20Frequency%20Solid%20Ferrite%20Cores%20for%20Round%20Cables&progroup=1.%20Round%20and%20Cylindrical%20Cores&part=HFB143064-300
provides about 180 ohms choke impedance.

Each slightly longer and in a lower frequency ferrite, 28B0591-200:
http://www.steward.com/web_part_no.asp?line=EMC%20/%20EMI%20Board%20Level%20and%20Cable%20Core%20Products&family=Ferrite%20Cores%20for%20Cables%20-%20%20Wiring%20Harnesses%20-%20Connectors&product=Broadband%20Solid%20Ferrite%20Cores%20for%20Round%20Cables%20and%20Wiring%20Harnesses&progroup=1.%20Round%20and%20Cylindrical%20Cores&part=28B0591-200
provides about 500 ohms choke impedance.

For the RG214, each Steward HFB259128-100:
http://www.steward.com/web_part_no.asp?line=EMC%20/%20EMI%20Board%20Level%20and%20Cable%20Core%20Products&family=Ferrite%20Cores%20for%20Cables%20-%20%20Wiring%20Harnesses%20-%20Connectors&product=High%20Frequency%20Solid%20Ferrite%20Cores%20for%20Round%20Cables&progroup=1.%20Round%20and%20Cylindrical%20Cores&part=HFB259128-100
provides about 120 ohms of choke impedance.

Each 28B1020-100:
http://www.steward.com/web_part_no.asp?line=EMC%20/%20EMI%20Board%20Level%20and%20Cable%20Core%20Products&family=Ferrite%20Cores%20for%20Cables%20-%20%20Wiring%20Harnesses%20-%20Connectors&product=Broadband%20Solid%20Ferrite%20Cores%20for%20Round%20Cables%20and%20Wiring%20Harnesses&progroup=1.%20Round%20and%20Cylindrical%20Cores&part=28B1020-100
provides about 300 ohms of choke impedance.

You will have to string these on the coax before terminating it.

>

As far as I know, these VHF arrays were only installed on the nose of twin-engined or four-engined aircraft. On a single-engined aircraft like the Spitfire, the antenna would have been behind the propeller. Did you mean the Mosquito?

There were also some rearward-looking VHF/UHF radars using a simple 2-element antenna, to warn of aircraft approaching from anywhere within a large rearward beamwidth.

A common feature of all these early airborne VHF/UHF systems was that
the antennas were fixed, so the view was always relative to the
direction of the aircraft.

>VHF and UHF radar has a better ability to peek over the horizon and at
>the time when reciever for uhf were still new tech offered the best
>range/power ratios.

Hence VHF/UHF was favored for shipborne use, where the horizon range is
limited by the relatively low antenna height.

>The magnetron moved effort to the milimeter bands
>at high power outputs where small high gain antennas were practical
>thus negating the need for high gain recievers.
>
Yup... and the small size eventually opened the way to steerable
antennas too.

TinyURL.com is a great resource for condensing very long web links that might become broken in transit. You only need to copy-and-paste the long URL into their web page, and "TinyURL" does exactly what it says.

The above example comes right down to:
http://tinyurl.com/n6bt9

How do you figure the lower "coaxial sleave" dimentions. My project is converting/cutting down a old model PD83 (Phelps Dodge brass skirt coaxial, aprox 50mHz) to 2 meters.

And I did use the ferrite bead on the J pole to cancel out the RF on the coax, but do not know which core specs.

The RAF Sunderland Flying Boat had a high wing and a deep hull with 4 engines. The Radar was ASV Mk 3 or Mk 5, a sea-going version of H2S. Sunderlands were employed on submarine hunting over the North Atlantic and Indian Oceans. 3000 MHz, 50 kW peak pulse power, radar range = 100 miles.

A radar scanner could not be installed under the nose. It had to be kept out of the water. Instead there were two syncronised scanners, one hanging under each wing tip. They rotated together, one scanner covering the port side 180 degrees and the other the starboard side.

The magnetron output was switched in the waveguide system between port and starboard, changing over at 5 degrees away from dead ahead to avoid spurious switching effects.

The parabolic scanners, rotating about once every two seconds, had a habit of getting out of sychronism when the aircraft made a tight turn. Something to do with gyroscopic, centrifugal and gravitational forces. It took 7 or 8 seconds to regain syncronism by which time the radar operator had got the target and other ships in the vicinity all mixed up with each other on the radar PPI display.

Aa the radar operator over the China Sea, I was once severely cursed (reprimanded) over the intercom by the skipper for getting ourselves lost immediately following a tight turn. But the war was now over and it was only a practice exercise.

Reg.

The FCC is not requiring specific testing for PSK31, RTTY,
Hellschreiber, Olivia, etc. and all those modes seem to be used pretty
extensively on all the bands. Not to mention, programs like MixW and
especially MultiPSK do an excellent job of sending a receiving CW. I see
all the modes continuing to flourish in the future even if a specific
test for one mode (CW) goes away.

The only issue with APRSPoint is that support and upgrades are sorely lacking. The Yahoo group he runs is censored so that any suggestions or criticisms of his product are not posted. He needs to really upgrade this program. It is one of the most expensive and also has the least amount of features. Nice start, but the author needs to really spend some time getting this program up to where all the other APRS programs are in functionality.

the concern is obvious for decades the CW crowd has relied on the
requirement to force all ham to at try it. mode welfare. they are afaid
without that stick the mode will die . it show a lack ocnvednce in the
mode

Even if I could learn the CW, I'm too stupid to pass the written test.

I have this congenital problem, you see. Life is NOT good for me.
I suffer from Microcephalic Dwarfism and I've been afflicted with it since I
can remember.
Definition: These syndromes associate growth retardation with
microcephaly and various facial anomalies.

My forehead is smaller than that of a normal person and my cranial cavity is
little larger than that of a Florida orange. My sloping forehead has only
one advantage in that it allows me to insert it into my rectal cavity with
little or no pain. While less than comfortable, and while it impedes clear
speech I am able to keep my ears warm in the coldest of climates, but those
are the good points.

I have suffered from extreme retardation all my life and have recently been
considering placing my head in the oven. I am betting that the accumulated
yeast in my mouth will aid me in blowing my head off at 350 degrees, thus
ending it all.

You guys have no idea of what torture it is to live with my afflictions. You will miss me when I am gone.

It's usually 1/4WL long. The theory is to turn that 1/4WL of
feedline into a transmission line where the currents on the
outside of the original shield are balanced by the inside
shield on the sleeve which balances the antenna currents.
It functions over a certain single bandwidth.

Reg, G4FGQ weote:
"As the radar operator over the China Sea, I was once severely cursed (reoremanded) over the intercom by the skipper for getting ourselves lost immediately following a tight turn."

On my ship, most of the crew was sleepless most of the time while we were underway. We had two 4-hour watches each day at our sea detail. Plus, we had to turn-to on our regular work details during dayrime hours if we weren`t on watch. But, the killer was the dawn and dusk general quarters positions we had to man every day while traveling in a war zone. You were really lucky if your assigned watch time sometimes cincided with work-detail time.

The result of all this sleep loss was some cat-napping on the bridge in addition to elsewhere aboard. Our top speed was 14 knots which made us faster than a liberty ship, so at times we got convoy escort duty. We had antiaircraft guns, 50 ca., 20 mm, and 40 mm. My gq position was on the latter.

Whenever the brdge awakened after a doze in convoy, someone would often shout down through the voice tube to the radar operator:
"Geez! how close is that ship ahead? Whereupon, the operator would push or pull himself away from a PPI tube covered with false sea return, poke his head out a porthole, then scream his best estimate back up the voice tube. That`s how he avoided being scolded.

Best regards, Richard Harrison, KB5WZI

I mostly agree with your definition of linearity. Roy's point that an offset in the straight line violates superposition is an example of a straight line violating superposition. Also consider the throwing of two dice. If the dice act independently they can be considered a linear system with two outputs (the numbers that show on the dice) which obeys the law of superposition. If, however, the dice collide when thrown, they now influence each other, the system becomes nonlinear, and the law of superposition is violated. It's pretty hard for me to attach a straight line function to dice.

Mixers are especially interesting beasts when viewed in the light of superposition. They are obviously highly nonlinear, yet we regularly speak of mixer linearity. Here is the trick: when the local oscillator is included in the input signal set, the mixer is highly nonlinear as the LO influences every signal that comes in drastically, in the sense of generating new frequencies.

But it is convenient to think of the local oscillator as just an internal parameter of the mixer, and to not include it in the input signal set. Under this assumption all the RF input signals substantially obey the law of superposition (that is, they do not influence each other) and discussing mixer linearity has enough meaning that we can characterize it through standard tests. Note also that under this assumption the output frequencies do not match the input frequencies in general, yet the law of superposition holds over a wide dynamic range.

Cecil's point that doubling antenna current will double the current at each point in the antenna (I'm rephrasing) has a dual in mixers: doubling any signal will double all the mixer's ouputs due to that signal alone, and not any other outputs.

Hmm...

You could build a 6 meter array of verticals, a four square or a
rectangle array or something. It may be a little touchy to adjust for
proper phasing, but it could be done if you've got your heart set on
phased verticals. You're not going to find a commercial phasing box
for 6m though. The only commercial transmit phasing unit I know of is
this:

http://www.dxengineering.com/Parts.asp?ID=893&PLID=174&SecID=85&DeptID=22&PartNo=DXE-TFS-1
P

And it's for 160, 80, 40...

If ice survival is your only concern, maybe you should just add heaters
to your yagi :-)

Good luck...

:Cecil,

I will start a little long as this is a peimo piece of 2" dia brass.
According to swr-freq by R. J. Edwards, the 2" dia sleave is about 50
ohms
for the 1/4 wave. 146 mhz, 51.1 ohms, jXin 0.0 .

My thaught is with the 1"mast inside of the sleave (insulated and
centered only connected at the top) what does the added capacitance do
to the sleave lenght?

And RFS does not have the old cutting charts for the Phelps Dodge PD83,
I tried that.

I'm sorry, I don't know what the velocity factor would be
in that configuration. If you sampled the common mode
current and tuned the frequency for a minimum, it might
give you an idea of the velocity factor.

Source record: 58457

I've gotten a few emails asking how a 1/4WL wire stub can be
used as a balun on a single band like 2m. Just connect the
wire to the element driven by the coax center conductor and
connect the other end to the braid 1/4WL down the coax. In
fixed font:

```
|
|
| Dipole
|
|
+====================================coax braid

+------------------------------------coax center conductor
|
| ==================+==============coax braid
| spacing |
+---------------------+
| 1/4WL stub
|
```

The current at the feedpoint sees a very high impedance looking
back down the *outside* braid of the feedline because it is looking
into a shorted 1/4WL stub. Often, a piece of similar coax is used
for the 1/4WL stub.

Back around the beginning of this thread a thought occurred to me, and I'm surprised that no one else mentioned it.

Unless we are planning on putting out ship on the great Salt lake, of one of the few other salt water inland lakes or seas, we're going to be putting the thing in the ocean.

Immediately, one sees that if a ground is at the surface of the water, at many points it will be 4 or more feet under the water. Dem boats rock! There are moments that it will be quite a distance under water, depending on the sea state.

Depending on the load, the water line is going to be different, and will be changing constantly as fuel and food is used.

Certainly any capacitive coupling through the hull makes for a variable capacitor? Does this have an effect?

Will we eventually come to the conclusion that we can't put radios on ships?? ;^)

Use a bare wire, and the top few inches will do the job regardless of how much additional wire goes below the water. As I've said before, there's no harm in having additional wire below the water; it simply doesn't do anything useful.

The problem is that as the boat rocks, the length of the wire to the ocean surface will vary in length, which will change the antenna's impedance. So a plate just inside or outside the bottom of the hull (or someplace that's always below the water line) would seem to me a better idea from a practical standpoint. Surely some boater who understood basic electromagnetics has thought about this and devised a method that's both practical and effective.

> Depending on the load, the water line is going to be different, and
> will be changing constantly as fuel and food is used.
>
> Certainly any capacitive coupling through the hull makes for a
> variable capacitor? Does this have an effect?

What will cause it to vary? In any case, just make the capacitance large enough so the reactance is always small compared to the ground impedance, then it won't matter.

Any theory that predicts any antenna can produce an H field without an E field, or that the H field is unusually large beyond a fraction of a wavelength from an antenna(*), is flawed. So you're free to make up any theory you like, and it'll be just as accurate.

(*) Or, from a receiving standpoint, that an antenna responds only to an H field or it responds more strongly to an H field beyond a fraction of a wavelength from the antenna.

Since the feedpoint impedance of a dipole changes as it blows
in the wind, guess we also can't use them on windy days.

Both services have their place. I would keep the CB and install a
multi-band Ham radio such as the ICOM IC-706MKIIG or a Kenwood or Yaesu
and a multi-band antenna to match. You will find both an adventure.

Upon a cursory search, it appears to me that "H-field antenna" is
probably another (perhaps misleading) term for "small shielded
receiving loop".

Discussions about the latter do seem to have the requisite amount of
lore, mythology, and strenuous disagreements as to just what this sort
of antenna does respond to and how it works.

> thjink?

Depends on how you feel about inbred hicks. If you're right at home with rednecks, white socks, and Blue Ribbon beer, CB may be your thing. OTOH, if electronic hole theory of semiconductor physics is more your cup of tea, ham may better suit.

Both camps can be serious as a heart attack about their equipment. My late FIL was an avid CB'er. He had the first Yaesu I ever saw. A $1600 model under a huge boom antenna on a rotating mast which he used to talk skip all over the country. His boat and car both sported illegal linears pumping top o' the line Cobras. I know he didn't know spit about antenna theory, and probably more importantly, didn't care. But, he knew who to ask and being able to do so on his rig is what it's all about, right.

While I, myself, was never attracted to long discussions with truckers about the merits of strip clubs or local gossip about the "new waitress down at Bubba's", I knew some of the local CB'ers and knew they were good people. CB, specially with respect to home stations, is just another mode of communication to them. This is more true in rural communities. The ham crowd, OTOH, by it's very nature of requiring a basic knowledge of science, tends to attract a more geeky element, a more literate slice of humanity. Not necessarilly better, or even smarter, just more educated and more into the technology of radio communications.

Try them both and then choose one or the other ...or both. Good people are good people, no matter the media.

Are you trying to pull our leg? A google search for "Chelton Loop"
antenna turns up only references to a street, Chelton Loop, in Colorado
Springs. If there's a "Chelton Loop" antenna, it must not have had
much written about it.

If you want to detect magnetic fields at HF, a small coil of wire
should work well. The size would depend on the size of the magnetic
field you're probing, and the spatial accuracy you want. If you want
to receive electromagnetic signals, as others have posted, be careful
about claims of sensing "only" the H field.

Cheers,
Tom

Thanks.

You do need to read a little more: by mentioning Doppler
> shifts, I was illustrating that a linear system can generate new
> frequencies without violating the law of superposition.

Hi Glenn,
I got that. Perhaps my use of "relativitistic effects" was inappropriate.
I still maintain that Doppler shift is not an example of (at least what I
would call) "creating new frequencies" because an electronis system did not
cause said shift. A system is linear or non-linear, but a system can't
"make Doppler happen". It is a frequency change, yes, but an "electronic
system" can't cause it. It occurs for reasons other than "system
characteristics". Yes, a space craft can be considered part of a system in
teh general sense, but not as I believe an "electronic system" should be
thought of when discussing such things. Perhaps symmantics in your view,
but not mine. I think it is a fundamental, but, perhaps can't explain
adequately why.
What a thread. usually when a thread gets this long it digresses far
outside the original intent.

Harbin,
You seem to understand the "J-Antenna". What you really seem to be asking is how far apart is "too far" for a balanced transmission line. That's a question I can't answer and I'm sure others can, but , in the common custom of adding obtuse references which sort of seem to be relevant... what about that old one wire transmission like the "G-Line"? [no joke]

73, Steve, K9DCI

Hi Steve:
I have read about the G-Line, which is very low loss (so claimed). Have
you heard of anybody that has used this line?

I haven't been following this thread lately, but happened on this
particular posting...

Seems to me you want to say "Linear TIME INVARIANT system" to get to
not generating new frequencies. Certainly I can build a system that is
linear but not time-invariant and generate new frequencies with that
system. A simple one is a signal going into a potentiometer, coming
out the wiper, in which the wiper is rotated continuously. It's
linear, but not time invariant, and obviously any input will be
amplitued modulated at the rate of the time variation.

Is a double-balanced mixer with LO a linear system (for input signals
in the intended amplitued range)? Increasing the input amplitude by
1dB causes the output amplitude to increase by 1dB, though the output
is not at the same frequency as the input. If the response of the
DBM/LO system to input x1 is y1, and to x2 is y2, then is (y1+y2) the
response to input (x1+x2)? Is a DBM/LO system time-invariant: if I
apply stimulus x1 at time t1 do I get the same response as if I apply
it at time t2 (where the response is also shifted by t2-t1)?

Perhaps this will be useful food for thought...

Cheers,
Tom

FWIW, Tom, "chelton" was probably a typo. There is
indeed a Chilton Loop Antenna at a research
facility in the UK. I think the name refers to the
loop used at the Chilton facility, rather than to
a particular antenna design.

You should go for your license. The additional privelages are quite
worthwhile. I will warn you that there are still quite a few inbred
hicks that got their ham tickets, unfortunately. The good thing is most
of them seem to be extra class, and are mostly older and will be gone
soon. It's a leftover effect of requiring Morse ability as opposed to
operating knowledge.

Can anyone tell me what the official name of the putty they use to seal the holes you run your coax through so bugs don't crawl in the wall or water doesn't get in? I like to get all my hardware type items from mcmaster.com. I'm sure they have it, if I just know what it is called I can find it on their website.

The box I have here says "One roll RTE62 R-type re-enterable sealing
material". RTE62 seems to be a 3M product type.

A similar product seems to be Google-able under the term "electrical
duct sealant" or "mastic". GB Electrical DS-110 is one type that
comes up... about $3/pound in quantity.

The problem with the newbys with nocode techs is that they don't realize
that knowing the code is just as important as knowing how to press the
on/off button.

I have some mastic but I thought that was just for sealing around
connectors not to seal the hole the in the wall the coax comes through.

Heck, my mother who was a legal secretary could go well over
100 wpm. On the old selectrics, I think she probably did 120-140+ wpm.
She made very few mistakes too. About like a typing machine..
I don't like responding while the other person is sending. At 55-60
wpm,
it could lead to some mistakes in copy.. :/ I do that on RTTY, PSK31,
but not CW. When I worked faster CW, I listened mostly in my head,
and only wrote down the important stuff like call, name.. But I sent
normally using a bencher paddle. I don't really use it like a squeeze
keyer either. More like an automatic bug. I side slap and rarely use
the squeeze method to make letters. I'm still using the same bencher
I have had for at least 20+ years.. Guess I'm getting my moneys worth..
I have a homebrew keyer that was built at the same time, and it still
works too.. :)

I recall a prof or two arm-waving over that one. However, I think if you formulate your definition of linearity properly, the transfer function y=mx+b will still satisfy linearity. Specifically, if the _response_ is the _change_ that occurs in the output going from x=0 to x=x1, then the response for x1 is (m*x1+b)-(m*0+b) = m*x1, and of course for x2, it's m*x2. The response for x=x1+x2 is m*(x1+x2), which is exactly the sum of the responses for x1 and x2.

Similarly, for a mixer/LO system with RF input and IF output, if the mixer is unbalanced and lets LO get through, it is still a linear system if the change in output when go from zero input to input x1(t) plus the change in output when you go from zero input to input x2(t) is equal to the change in output when you go from zero input to input (x1(t)+x2(t)).

But note that a mixer/LO system is NOT time invariant, because the output for x1(t+delta) is in general NOT the same as the output shifted in time by delta for input x1(t).

You can most certainly find text books that define linearity differently than I did above. I find the definition above to be a more useful one, however, and it seems to be the one generally accepted in practice, even if it's not stated accurately in words.

Cheers,
Tom

It's not clear to me whether you're proposing an alternative definition for linearity or for superposition. I've never seen superposition defined as other than that the sum of responses to individual excitations be equal to the response to the sum of the excitations -- that's the definition in Pearson & Maler's _Introductory Circuit Analysis_, Van Valkenburg's _Network Analysis_, and the rather old edition of the _IEEE Standard Dictonary of Electrical and Electronic Terms_ I have. Do you have a reference that gives the definition you propose for superposition?

If on the other hand the alternative definition is only for linearity, we'd then be faced with the possibility of having a linear (and time-invariant) circuit which doesn't satisfy superposition. That's not a pleasant circumstance to ponder.

There seem to be two possible kinds of "Chilton loop".

One is at www.chilton.com, which is a web-controlled SW radio receiver
located in the USA. This is just a loop of wire in some guy's attic.

The second kind may be related to the ionosondes located at the
Rutherford Appleton Lab, Chilton, UK; and at Port Stanley, Falkland
Islands. These do use crossed loop antennas (as the referenced picture
shows)... but in 25 years living just a few miles down the road,
including 12 years of working right next to RAL and regularly eating
lunch with the hams who work there, I never heard or saw the term
"Chilton loop" until yesterday, right here.

However, I will make some specific inquiries about those loops.

Now if you want something really serious to talk about, those
RAL/Stanley ionosondes are being closed down! The scientists who work
there are horrified, because it would pull the plug on a major
international source of daily data, and terminate the world's
longest-running continuous sequence of ionospheric observations:
http://www.wdc.rl.ac.uk/wdcc1/news/closure_notice.html

(This actually looks like a clumsy political move to shift the running
costs away from the UK science budget and find some other source of
funding, using the threat of closure as a way to get attention. But
suicide bids of this kind can occasionally go wrong...)

There is a company named Chelton that makes antennas listed on the web.
Shows reference to a lot of military stuff. If they are claiming they have
an H antenna then.....

Lest anyone think that the addition of an offset term (the b in y=mx+b)
violating superposition is merely of academic interest, analyze a
direct conversion receiver. At my shack I have a Softrock 40, which
tunes about thirty KHz of the 40 meter band. At the center of the
spectrum (which corresponds to the mixer converting to very low
frequencies and DC) is a 1/f bump that the designers have attributed to
mixer 1/f noise. But it is not noise at all. When tuned in, it is
full of strong signals and strange sounds. These are distortion
products, and are caused mainly by the b term in the detector used on
the receiver.

They wipe out about 3% of the receivable band.

Sometimes the b term is benign, but not in this case.

That is a very good point that I never considered. In thinking about it,
it makes perfect sense. "Mode Welfare" - too funny.

I don't think you can really expect the newbies to want/desire to know that which they know may be being phased out soon. Why worry about learning it if they know it will soon be gone?

I am of the opinion that a 5 WPM at least - should be kept on as a requirement - as someday - it may be needed. Think not? Say you're in the midst of an attack - of terrorism, a war on our homefront OR a large scale natural disaster, a microphone isn't working or available. You can key the radio but don't know code - now what? With code, even at 5 WPM - you could get some very important information to those needing it to help save you - to them. You could tell them WITH code, what is needed, exact whereabouts, how many people involved, etc..... Just clicking a mic pin with a wire won't tell anyone anything and could delay any help or a response big enough to do much good. In these times with the large scale disasters as we've seen and attacks - even for any said to be planned, NOW is a good time to WANT to know code. IT may save you..... It is one of those skills you learn - just like CPR or whatever - you hope you never have to use, but you're glad you have it - when you need it.

5 WPM is NOT hard to learn or do. ANYONE with any interest can learn it in a month at most if you take x amount of characters a day and start using them. Many learn it sooner but it shouldn't take more than a month to get to 5

WPM. "I" know how I learned it but my method won't work for all, just as others didn't work for me. But the main thing is, you must "want" to learn it. If you were 16 and didn't want to learn to drive a car - plain and simple your driving days would be non-existant or very short lived at best- point being MOST 16 year olds WANT to learn to drive. YOU HAVE TO WANT IT.

Many of you may have heard of the Quecreek Mine incident in PA some time ago. A pipe was drilled down into the shaft. Those at the surface heard 9 taps on it, signifying there were 9 miners there. NOW - if any of those miners KNEW code, they could have gotten a message to the surface as to what conditions were exactly, the extent of injuries as best they could, etc. Maybe even instructions to help those on the surface plan their moves a tad better. Luckily, the 9 were saved but that is an example of just those 9 taps - crude MORSE - which sent a valid message. Were it not for that, no one would have known they were alive until someone may have went in. AND - MAYBE - those digging operations after a couple hours would have slowed due to lost hope. The fact they knew those guys were still alive gave them urgency to press on..... Code CAN have a place in your life.

One other thing..... I cut my teeth on CB back when the FCC was busting CBers regularly for violations. I then got into Ham and Electronics. ALL radio services "CAN" and "DO" have a place when it comes to chatting, information exchange OR emergencies. ALL groups "can" work in unison for the betterment of mankind if desired. Ham has it's place. CB was used mostly by those such as "Auxiliary Police" - where not everyone had to have a "code" much less a license to have studied for - to use radios for their purposes. SEAT-REACT when operated properly was as useful as the Ham groups for emergencies.
At one time, I belonged to REACT and some local Ham groups. I'm heavily involved in Public Safety - so I got the best of both worlds. The REACT team died and if I'm not mistaken, maybe the founding unit. Believe me - in a HUGE disaster our fire band was SWAMPED. Ham and CB alike WERE IMPORTANT. I had information on both coming to me - which was of enormous help. I was getting information that was not able to be had via the Fire Radio - due to it being so laden with traffic. I often use FRS radios now too - to avoid tying up the Fire Frequencies here. I USE WHAT I MUST to get the job done.

Pull the cable out of the wall from hte outside by a couple of inches, place a good dollop of silicon caulk (the same stuff you use to caulk around your windows) about an inch or two from the wall then pull the cable back inside. This will make a custom fitted grommet . Dress the cable downward from the hole so water run away from the hole. Think drip loop

OK, let me display my ignorance once again.

There are many construction articles about ferrite-core antennas for the low bands. (Not to mention all the ferrite-core antennas in AM receivers.) Are these not H-field antennas, to a large extent?

3569. Jury-rigged SMA connector

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-06 17:03:04 UTC
From: NathanielColson@gmail.com
Message-ID: <1149613384.452791.180750@i39g2000cwa.googlegroups.com>
Source record: 58409

I'm a UCF student working on an indoor mobile robot positioning system based on RFID, and I want to connect the SMA cable of a 13.56MHz single-loop antenna to two pins of a straight-pin header on an RFID reader.

My question is, will the characteristics of my antenna be shot to pieces if I just solder jumpers from the contacts of the coaxial SMA cable to the two header pins? Is it going to cause noise, interference, etc. to use those two straight wires for a short distance instead of the central wire and braided sheath?

antenna:

3570. Well, I got my CondoBuster antenna up

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-06 17:33:54 UTC
From: sanktgilgen@gmail.com
Message-ID: <1149615234.018536.244700@g10g2000cwb.googlegroups.com>
Source record: 58410

So, I bought one of those CondoBuster 10 12 15 17 and 20 meter antennas that the guy sells on ebay for $20. It came last week and I hand the maintenance guy, who is also my fishing buddy, come over on Saturday to help me put it up.

I live on the top floor of a two story condo building. We have a peak type roof that extends out over about half of our balcony. So, what we did with install this antenna, which is an off center fed dipole, as an inverted vee from the peak on the roof and then ran the legs down the end of each of the roof sections. The antenna was mounted with little C shaped stand off insulators. The antenna is black and the insulators are black so it is real difficult to see if you are more then 15 or 20 feet away from it.

I connected it to my Kenwood 850 and made a couple contacts on 20 and a couple on 17. The antenna appeared to work quite well. But I wanted to find out just how well it worked compared to the antenna I was using. For the past 4 or 5 years I have been using the older model of the B&W Cliff Dweller antennas. Not the newer one, but the older one that has the interchangeable coils. It is just one hell of a good antenna.

So, anyhow, I went over to a friend's house and borrowed and antenna switch, brought it home and connected both the CondoBuster and the B&W to it so I could switch back and forth. Well, the guy who sells these says you will be amazed, and I was. Generally there was a difference of between one to three S-units on a given signal on the receive site and about one to two S-units on the transmit side. The difference is profound.

I am feeding it with RG-58U. No balun, the antenna tuner in the 850 matches it perfectly. I am just happy as hell with the antenna. It is the best 20 bucks I have ever spent on ham gear.

No it won't be a problem. You just need to keep such leads short with
respect to a wavelength at the frequency of operation, and, well,
13.56MHz is around 20m wavelength, so you won't have a problem with a
couple centimeters of wire.

Personally, as a matter of style, I'd probably solder a mating SMA
connector directly to the header using the shortest possible wires and
then add some hot glue or epoxy to mechanically stabilize the connector
to the header, but that's just me :-) It makes it easy to add more
cable later if you need.

You could also cut the SMA off the cable and solder the coax center
conductor and braid to the two header pins. I feel like it's probably
pretty easy to short out an SMA with solder blobs.

Only very locally, and only to a limited extent.

When a signal originates far from an antenna, the response to E and H fields is in the ratio of about 377 ohms, the impedance of free space. This is true for *all antennas*. In other words, all antennas have the same relative E and H response to signals originating far away.

Very close to a small loop antenna, response is greater to an H field than E field. It does respond to both, however, as all antennas must. As you get farther away from the antenna, the response to the H field decreases in relation to the E field response. At around an eighth wavelength distance from the antenna, the response to E and H fields are about the same as for a distant source. Beyond about an eighth wavelength, the response to the H field is actually *less* than the response to an E field compared to a source at a great distance. The ratio of E to H field responses then decreases to the distant value as you get farther from the antenna.

In summary, the antenna responds more strongly to the H field if the source is within about an eighth of a wavelength from the antenna. Beyond that, it actually responds more strongly to the E field relative to the H field than a short dipole or many other antennas -- you could more properly call it an "E-field antenna" in its response to signals beyond about an eighth wavelength. The difference in relative E and H field response among all antennas becomes negligible at great distances; for antennas which are small in terms of wavelength, the difference becomes negligible beyond about a wavelength.

Now, suppose you could make a magic antenna which would respond only to the H field of a signal originating at any distance from the antenna (which is impossible). What advantage would it have over a real antenna? Remember that the E/H ratio of any signal originating very far away is 377 ohms, regardless of what kind of antenna or source it came from.

Not by tapping. International Morse requires dashes as well
as taps (dots). There is a tap code used in prisons that will
accomplish communications under those circumstances. And since
more people have been in prison than hold an amateur radio
license, seems that it would make more sense to require knowing
the tap code than to require knowing International Morse code.

Search on H-field antenna. Then click on "Standard H-field NRSC antenna -Chris Scott and Associates. The LP-S series stanard H-field Antenna is specifically designed for emission measurement of AM broadcast stations using a spectrum analyzer or other calibrated receiver.

There seems to be a number of commercial antennas
described as H-field antennas intended for LORAN
application. Most claim improved immunity to
precipitation static. Is there a theoretical basis
for such claims?

Thanks.

Chuck

DUH - I KNOW THAT - I was just saying the tapping let the people at the surface know there were 9 people down there. MORSE CODE - "could" have relayed much more info if one of them knew it. REREAD my message.....

I am fully aware of what "code" is, I'm an Extra myself - have been for quite some time. I am also a VE Test Team leader.

Yes. It increases sales just like zoom zoom zoom in car advertisements.

Seriously, precipitation static is caused by corna discharge from an antenna or object someplace near the antenna. The radiated field from that leakage current can be almost any field impedance and will always be a mixture of time-varying electric and magnetic fields.

What a small loop actually buys you is a compact antenna that has no sharp protruding edges, and that decreases the chances of having corona right from the antenna. A whip would have a sharp protruding point, and that would encourge corona discharge and the resulting noise we call "precipitation static".

Other than that, there is no advantage.

I think the precipitation static talked about is
caused by the accumulation on the antenna of
charges carried by precipitation particles (e.g.,
snow). Apparently this is a common problem on
aircraft antennas, and hence the interest in LORAN
antennas with better immunity to the accumulation
of precipitation charges.

Doesn't sound like a simple antenna geometry issue
and it doesn't sound like a corona issue.

Which is not to say it isn't all hype, but
wouldn't the charge on the antenna simply
redistribute itself over the body of the aircraft
(assuming it is metal) and not accumulate on the
antenna as it would were the antenna insulated
from the aircraft body?

Chuck

K7ITM wrote:
"If you say that in the system (y = mx + b) that b is the response to zero input (x=0) then you will conclude the system is nonlinear."

Why? the factor (b) is a constant, a value to be added to (mx) to total a value for (y).

(mx) is a straight line. Every value of (b) produces a straight lline parallel with lhe line y=mx when b=0. Factor (b) is merely the offset value of the sloped line in the x direction.

y=mx+b is listed in math books as a defining example of a linear equation. (When plotted, a linear equation produces a straight line.) y=mx+b has a special name: "The point slope formula". Perfectly descriptive, too.

To clarify everything, graph a few values for yourself.

Boy it's fun what a little trolling can do to my peers. I'm also an
Extra, and licensed for 29 years.

Code is worth what it can do, but has had less and less to do with the
hobby for decades. It's a great hobby within the hobby on HF, and was
the core of EME for years. It still is to some extent, but advances due
to moving up in frequency as well as computer based modes as low as 6
and 2 meters are making it something used for EME as much for fun and
stubborness as for usefullness. SSB is a very popular mode on EME now
among the big guns.

CW is dead as far as being needed. It's a great thing to have as a
skill, but is now as needed as spark.

The person who said they could key an HT to send CW was stretching it
way beyond reality. Ain't gonna happen, any more than someone will make
a spark transmitter by keying a big bunch of wire they wound in a coil
when trapped in their basement by touching it to the hot side of the
drop in their fusebox.

Hi Chuck,

Snow, rain, dust, soot, anything airborne which in fact is the principle carrier of current from earth to air in the current cycle that feeds the electrostatic potential of lightning clouds (which amounts to about 600 V/m).

>wouldn't the charge on the antenna simply
>redistribute itself over the body of the aircraft
>(assuming it is metal) and not accumulate on the
>antenna as it would were the antenna insulated
>from the aircraft body?

Charge moves to the smallest radius surface, and once there, if there is sufficient flux will break down insulators (air being one) and arc-over (corona discharge). One solution is to reduce the number of small radius surfaces (pin-points) and loops qualify (vastly larger radius than a monopole tip). However, and at altitude, if the loop is in fact a square, then the corners are prone to discharge. HCJB antenna design tested this at altitude in Quito, Ecuador and they solved it by moving the feed point so that the high potential fell in mid-span, instead of at the corners. Auto manufacturers also had to contend with the problem, they put small round caps on the ends of their car antennas.

I'm not sure if you're referring to my post or someone else's who I didn't see. In "my" example - I was saying if a MIC was broken and they knew code, they could short out the tranmit pins - like making and breaking contact such as a key would do - to broadcast a coded message. It "can" be done. There is what is/was known as "Modulated CW". And, I've seen guys key an H.T. OR Mic and do code with an "Oscillator" with the other hand - thereby transmitting the code - from the Oscillator speaker through the mic of the H.T or radio. Maybe that is what "they" were referring to - I don't know.

Then too along with the above - they "could" have been referring to using the "key pad" to send code while the H.T. was keyed OR using the keypad on a mic while it was keyed..... If memory serves me correct - at the moment (slips at times) - THAT would be equivalent to MCW (Modulated CW). I've seen that done too.

But according to W8JI "teachings" there is no way that electrostatic shield
on a small loop antenna would work as a shield, attenuating E field dominant
signals or noise generated within that 1/8 or about wavelength.
According to him, it works as an antenna. Some scientwists can not
comprehend that electrostatic shield shunts the predominantly E field
generated in the vicinity. It is the FACT, easily observable by anyone
building shielded small loop and having TV birdies, PS bricks or arcing
noise source within about 1/8 of a wavelength.

W8JI wrote:
>>Seriously, precipitation static is caused by corna discharge from an
antenna or object someplace near the antenna. The radiated field from
that leakage current can be almost any field impedance and will always
be a mixture of time-varying electric and magnetic fields.<<

Roy, 'splain to him about this 1/8 or so thing. He still dungetit.

I was thinking "electrician's putty" or similar -- what we used to call
"monkey shit" in the Navy, but I couldn't get a good match on Google for
those terms. While mulling this over, I remembered also Plumbers Putty.
While generally not used for coax, I have used it under sinks and in the
garage for sealing around pipe penetrations. What I have is light tan in
color. It stays soft and flexible (but I don't know what sunlight does to
it or whether it will take paint). It's cheap and available and might be
just what you need.

I seem to remember that the original Morse code was all clicks. I think the telegraph lines were DC current to electromagnetic clicking "receivers". The dashes were sort of implied by the spacing of the clicks...not that it matters to the antenna group, I guess.

The only thing good about the prison system of taps mentioned earlier in the group is that if you know the grid, you know the "code". Extremely inefficient, however.

3605. End-fed wire question.

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-07 04:34:26 UTC
From: blair thompson <blairt@abcomm.ca>
Message-ID: <0ukc82prneu4c8u1pdnpe132g06353kvk2@4ax.com>
Source record: 58296

I have a 63 ft. end-fed wire antenna which I am using with an MFJ-949 versa tuner, and 4 counterpoises cut for 1/4 wave on 15,20, 30 and 40 meters. Far end not very high, about 25 feet up a tree, shot up there with a slingshot. Pretty thick foliage right now, but not a lot of the wire is showing and in the clear as the near end of the wire slopes down almost to ground level (townhome QTH).

Bit of an underperformer, and I was wondering whether it would be worth my while to install a ground rod in order to ground the tuner, and whether that might improve matters a bit,

Thanks for any information.

How about a fast double tap on the pipe (or bar) to signify a "dash"? It's not an elegant solution, but could be made to work. Those guys are probably not gonna try for 30 characters per minute anyway.

==========
Blair,
A single ground rod will be virtually useless - that is unless it can be driven into salt sea water.

If the radials are elevated above ground, then some improvement may be achieved by allowing them to rest at ground level. This will increase the effective height of the antenna.

Better still, shallow-bury them.

Even better, add more radials. Extra radials, on or underground, need not be very long and not of any particular length. The more there are up to a dozen or so, the merrier.

Important - try to get the near end of the wire as high as you can in the air. Get some vertical wire into it. Can the near end be taken up the side of the house and suspended from a chimney, TV antenna or rain gutter or something? This will definitely make a noticeable improvement.

Reg.

3608. Re: H FIELD ANTENNAS?

Source record: 58299

Precipitation static, eg., from highly charged raindrops and fine snow
or fine sand, impinging on the antenna wire, just causes an increase
in receiver white noise level. It can be reduced but not removed by
using a very thickly insulated antenna wire, like the inner conductor
of a coaxial cable complete with its polyethylene jacket.

Reg.

3609. Re: H FIELD ANTENNAS?

Newsgroup: rec.radio.amateur.antenna

From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <CIydnYr6UbGs6hvZRVny3w@bt.com>
Source record: 58300

The only useful purpose served by making a loop antenna from coaxial cable is to ensure capacitance balance of the loop against ground, so sharpening its directional nulls and, incidentally of course, to support the very thin inner conductor which would otherwise collapse under its own weight.

The outer coaxial conductor has no effect on signal to noise ratio as perceived by the receiver. S/N ratio depends only on what's contained in the local field itself.

If there's any difference in S/N ratio due to use of a tuned loop, as with a magloop, then it is due to the loop's very narrow bandwidth - not the shield.

Reg.

I've never seen a case of precitation static occuring that way.

In every single case I've seen, whether on tall buildings, tall towers, or antenna hear earth, it has always been corona discharges from the antenna or objects near the antenna.

How do I know this?

1.) I had side by side "insulated" and "unisulated" Beverage antenna wires that are otherwide identical except for being spaced a few dozen feet apart, and the antebnna pointed towards my tall towers had precip static and the others did not. Both were equal in noise despite the fact they are hit by the same rain or dust.

2.) I have Yagis on towers that are identical, and the LOWER antenna almost never has precipitation static despite the fact they are hit by the same rain or dust.

3.) I've had dipoles at various heights, and the lower dipole always has much less precipitation staic than the high dipole despite the fact they get the same rain or dust.

4.) The period of the noise has nothing at all to do with the number of droplets hitting the antenna. It increases in pitch as the charge gradient between earth and clouds builds, then when lightning flashes it immediatly stops without time delay.

5.) On tall buildings on dark nights in storms, we could actually hear the same pitch noise as the repeaters rebroadcast, and walk to the noise source and actually see the corona.

6.) Antennas in fiberglass radomes were no quieter than bare metal dipoles on tall buildings.

7.) I even used an electrostatic sprayer to charge droplets and hit an antenna, and could only simulate noise when the antenna element had a sharp point and I got near the sharp point...at which time I could see faint corona.

End fed wires must always be used against an efficient ground system consisting of a large number of radials or a tuned counterpoise for each frequency.

A single ground rod is normally fairly poor.

The CFA proponents weren't sophisticated at all. The "inventors" probably
read half of chapter one of an undergraduate electromagnetics textbook but
forgot to read/understand the rest. Another source of embarrassment was
that one of the CFA backers was a university EE professor. Go figure.
Extraordinary claims but no extraordinary proof. BTW, in case you're
interested, the British/Egyptian inventors' U.S. patent number is
5155495. It's patented so it must work... 73s from N4GGO,

Dear Tom:
Your message may one of the most interesting and unexpected that I have read in a long time. Some comments follow. Please note my extreme reluctance to engage in anything but a calm exchange of experiences and opinions. I have no interest in provoking you.

Your experience does not seem to agree with experience at remote, flat, treeless sites here in Michigan. Please note the qualifiers in the last sentence. Especially in the UP of Michigan, at certain times of the year, P-noise is the major factor in limiting radio use.

P-noise is not found on an antenna imbedded in a clump of trees when an antenna out in the open (many wavelengths from the first antenna) has P-noise. The follow-on is that since most sites are urban or suburban, few radio amateurs will experience P-noise.

P-noise is observed when there is no rain nor thunderstorms, but plenty of wind. This is suggestive of moving charge discharging into the antenna. Of course, one could define this action as being "corona." Of course, if one places enough charge on a piece of metal eventually there will be "corona." Many antennas have a conductive path to earth that makes such an accumulation of charge unlikely.

There is no doubt that an antenna experiencing P-noise will radiate and thus noise will be received by nearby antennas. That is why successful receiving antennas here in the flatland are placed a long distance from metallic objects.

Most people have never heard P-noise because their site precludes same.

A paper published in August about 1961 (IEEE Vehicular Transactions) is one of the few references that has been published that deals with means for reducing P-noise. The article involved a fixed, not mobile, antenna. It appears that additional work has not been published that deals significantly with fixed antennas. (Lots of papers exist dealing with aircraft antennas.)

Your #6 is interesting. Unfortunately, there is so much radiation from what else is on a tall building that it is difficult to sort out where excess noise is coming from. An antenna inside of a slightly conductive radome that is placed a long distance from anything that could radiate might be different.

Your #7 is especially interesting. Our EMC group has on the drawing board just such experimentation. We will be on the lookout for "end effects." Your note is a valuable observation.

Regards, Mac N8TT

==========
Tom,

The description "precipitate" clearly applies to what is being precipitated onto the antenna, eg., rain drops, hail-stones, snow particles, sand particles in a sandstorm, etc.

When charged to a high potential, on impinging on the antenna wire, the charge on a particle is suddenly released causing a click in the headphones. A very rapid succession of small random clicks constitutes white noise.

I, and everybody else in the uK, have experienced rain static dozens of times, sometimes 10 or 20 dB above S9 on the S-meter. At the start of a rain storm and when nearing its end, individual clicks can be heard. As expected, when the clouds are most highly charged, the noise is most intense when there is thunder about. It can amount to a roar. It is loudest on the lower HF bands and at MF but that may be due to the physically larger antennas.

What you have been suffering from is not precipitation or rain static. You should give it a different name. If you have never experienced rain static, perhaps you disconnect your antenna when a thunder storm storm is approaching and before it starts to rain.

Reg.

I experienced that kind of static in Arizona with wind, extremely
low humidity, and bare wire. I've never experienced it in East
Texas.

During long boring meetings at an Aerospace company, my buddy and I would send Morse by pencil taps, sharp tap was a dit and a tap-scrape was a dah. Worked well until a new manager gave his fist talk assuring us nothing would change - we tapped out BS.

After the meeting, the new manager asked my buddy and I to stay for a moment after the meeting,

With a smile, he sed Hi guys -- I'm W⌿XYZ

Real call sign disguised to protect the guilty (;-)

In which case, it will be practically perfect! Not
much gray area for ground rods in this
Zoroasterian space. ;-)

Well, as far as ground rods are concerned, it
would be practically perfect, but your antenna as
is would still not be.

If the antenna is roughly a half-wave on 40
meters, mostly horizontal, I doubt that more
radials will help much.

>
>

If you are seeking more low-angle radiation for
DX, then this will help and you may see more
benefit from additional radials. You might
consider attaching the guy to the chimney, etc.,
and running the "vertical" wire from the tuner up
and away from the house. You don't want that
vertical wire running right alongside the chimney
or TV antenna support.

Chuck

The first Morse machines scribed the dots and dashes on a moving strip of paper. Operators of the day found that they could decode the sound of the scriber by ear, so the scribing machines were scrapped.

Because, from 3.3, 'Network Theorems,' in "The Electrical Engineering Handbook,"
Ed. Richard C. Dorf, Boca Raton: CRC Press LLC, 2000 (you can find it online),

"The superposition condition: If the input to the system, e1, causes a response, r1, and if an input to the system, e2, causes a response, r2, then a response, r1 + r2, will occur when the input is e1 + e2."

If you take the response to x0=0 to be b, then the response to, say, x1=1 must be m+b, and to x2=2 must be 2*m+b. Then for superposition, and therefore for linearity, the response to (x1+x2)=3 must be m+b+2*m+b = 3*m+2*b, which it is not: it is 3*m+b. I do not suggest a change in the definition of superposition or of homogeneity (which seems to be simply a subset of superpostion anyway) or of linearity. I only suggest that "response" be interpreted as the change in output which occurs when you go from input a to input b. I've generally not seen "response" to be very well defined in those texts which define linearity, though it's quite possible I've missed it. In the PDF file for all of Chapter 3 of the book quoted above, it is certainly not.

I guess I'd prefer, basically, to say that the following relationship defines a linear system (MIMO even) -- but it is NOT sufficient to describe all linear systems:

dx/dt = Ax + Bu
y = Cx + Du
where u is a vector of independent input variables, y is a vector of dependent output variables, x represents state variables for the system, and A, B, C and C are matrices of coefficients which are constant in a time-invariant system, but which may be variable with time in a system which is time variant.

Cheers,
Tom

So I "don't get it" because I (and others) see the difference in reality,
when electrostatic shield suppresses the local interference. You explain
behavior of E and H field in the vicinity of antenna but that does not apply
to "W8JI shield is the antenna" and "current at both ends of the loading
coil is always the same".

I will stick to my reality handle, rather than joining scientwist's chorus.

> What advantage would it have over a real antenna?

I read the main reason was less electrostatic interference
but with less immunity to strong nearby stations. Does
the magnetic field really have less noise than the E-field?

Polarization is also an interesting component.

Isn't this the triboelectric effect? I read this was a big problem for
certain newer wireless applications.

Energized TV antennas always feel 'gritty' when I brush my fingers
lightly across them. Why is that? I also get a very mild shock
sometimes, but that gritty electric sandpaper friction is very strange.

Also the indoor TV antenna collects dust and vaporized
cooking oil like there's no tomorrow. Is this like a Tesla coil?

For the 1980's CA 75m mobile antenna shootouts, a ferrite
rod antenna was used for receiving because the local human
bodies had much less of an effect upon it than, for instance,
upon a hamstick antenna. I always assumed it was because a
human body has more of an effect on the E-field than it does
on the H-field.

Source record: 58320

I understand that E and H fields are intrinsic parts of the same thing (for radio waves, etc), and I am not trying to separate them along the lines discussed by some list participants.

I would think that the E and H ratio of 377 is a function of the SI units of measurement involved. It would seem that there is the same amount of energy (at different and selected instances) in the E and H waves, and different units of measurement could produce a ratio of 1:1 (or anything else, with appropriate units of measurement).

To return to the ferrite rod antenna: Ignoring the directional null capability (which might be very useful in some real-world circumstances) is there any advantage to a small ferrite rod antenna over a short wire antenna (assuming perfect amplifiers, as needed, following the antennas and assuming 160m or 80m usage)?

As mentioned earlier, there have been a number of construction articles over the years explaining how a ferrite rod antenna did wonderful things for 160/80 operation. I have wondered if these results are generally valid, or were the result of the authors' pride in their works, or happened because the directional null abilities solved a local problem.

I use the "expandable foam" that comes in a can about the size of a
spray paint can. There are two types. The yellow foam that expands
and gets hard which also is sensitive to UV which will cause it to
change color (darken). Don't use this around areas where the pressure
of expansion can cause problems like sealing around a door.

They also have a "soft/flexible" version that is white and costs a bit
more. It's what I use to block the large conduit between the tower
and basement. http://www.rogerhalstead.com/ham_files/cablebox.htm
Shows the conduit at the tower and coming in the basement. I just
squirted the stuff in. I wasn't worried about it being pretty, just
effective. With care you can be a lot more artistic. <:-)) It's easy
to apply and easy to remove when necessary. Bugs and critters appear
to not like the stuff. I like it far better than the putty.

The yellow foam is a tad over $3 USD a can while the white, flexible
stuff is $4 or $5 a can. Both are usually available at Lowe's,
Builder's Square, and hard ware stores.

The choke balun made from a small coil of coax would be easier to make. At my previous QTH, four turns of about 6in diameter made a big reduction in the levels of noise and birdies on 6m (even though those coil dimensions weren't optimized in any way).

This kind of feedline choke is simple, cheap and low-loss, so by all means go ahead and use one. With a 3-element quad, you should be able to position the coil at the feedpoint while supporting its weight from the mast.

3634. Yet another 6m 3el Quad question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-07 17:22:22 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <jXDhg.37830$4H.24271@dukeread03>
Source record: 58327

My Quad is all built and I'm waiting or FedEx to deliver my rotor. I built the quad out of wood, with a 1-1/4" dia pine boom and 4' mast plus 1/4"x48" spruce dowels for spreaders. I used insulated 16g stranded wire for the elements. All the wood is either painted or treated with sealer.

Problem is I just broke a spreader moving the antenna and I'm worried about how fragile the whole design is. Would the performance change much if I used 1/4" aluminum rods instead? Maybe I should just get some fiberglass resin and paint the spreaders with several coats? How about wrapping them in re-enforced boxers tape (the good stuff with fibers in the tape)?

Thanks for the help, guys....

3635. How to model linear loading in shortened dipole of vertical using EZNEC?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-07 17:25:44 UTC
From: "Steven R. Jones" <srjones10@cox.net>
Message-ID: <pan.2006.06.07.17.25.41.157132@cox.net>
Source record: 58326

I want to work out a design for a linear loaded off center fed vertical
dipole for 75M (perhaps will work multiband as well?) using linear loading
in an "S" configuration, i.e:
feedpoint
I----------------------------------()-------------I
I I
I----------------------------------I I------------I
I I
----------------------------------I I-------------

Which per my reading should let me design a 75M vertical that is only 60%
of the length of a conventional radiator. A recent article in QST showed
the successful use of 450 ohm ladder line with interwoven 3rd wire as a
conveient way to build this sort od linearly loaded design. In attempting
to model this design in EZNEC, I do not seem to get the loading effect and
shorter length of the radiators to achieve resonance, nor do I get the
feedpoint impedance lowering that is described for this sort of loading.
I was hoping that the OCFD design would allow direct feed through a choke
balun without having to deal with impedance transformations. with either
an excessively low center feed impedance (with loading) or the typical
~200 feedpoint impedance and 4:1 balun required with the OCFD design at about 1/3 distance
from
one end.

Any thoughts or prior experience to share?

Steve

All licenses should be terminated, immediately, and future testing will be a minimum of 110 wpm Morse code in a language that the applicant does not know. All sent straight key.

Written tests will be changed to essay type. The applicant must demonstrate mastery of all aspects of RF discipline at the PhD level. Since people can look up answers in a book as well as a test question pool, all work must be new and cutting edge. Any answer that can be found in a book will disqualify the applicant.

Upon the successful defense of the applicant's thesis, a 20 year waiting period starts. The work done by the applicant in pursuit of his license must be demonstrated to have a lasting and profound effect upon the RF discipline and especially so on the Amateur radio community.

There may only be 2 hams left, but just imagine how superior they can feel about themselves........

My reality, and Tom's, fits with the clear explanations in Johnson's _Antenna Engineering Handbook_ (successor to Jasik); King and Harrison's _Antennas and Waves_; King, Mimno, and Wing's _Transmission Lines, Antennas, and Wave Guides_; and undoubtedly others, since it comes from basic electromagnetic principles.

I explained the nature of the E and H fields from a small loop antenna. This is the sum of the fields from each part of the loop. It is not representative of the field in the small region between the wire and shield of a "shielded" loop, as you seem to be trying to infer.

If you'd spend a fraction of the time studying that you spend desperately trying to find something wrong with anything Tom says, you'd have a much better understanding of how antennas work.

Yes, that's correct. What I tried to do in my explanation was to relate the E/H ratio near a small loop with that of free space. That makes the units of measure immaterial.

You get a greater effective aperture (aka "capture area", and directly related to "effective length") from the ferrite rod antenna for a given physical size. This results in a larger signal for a given impinging field strength. If you had perfect amplifiers, that would make no difference, but real amplifiers generate noise, so a larger signal results in a better signal/noise ratio when you're at the level where the amplifier noise dominates the system noise figure. But if the signal level is large enough so that atmospheric noise dominates, having a greater aperture doesn't present any advantage.

Anecdotal reports of "wonderful things" should always be highly suspect, and placebo effect high on the list of possible causes. It might be easier to get a good null with a ferrite rod antenna than with a casually built antenna of some other kind, and that would be a big potential advantage.

When considering the value of anecdotal reports, consider the widely reported benefits of various kinds of speaker cable, and the staggering amount of money that's being extracted from the believers.

> A single ground rod is normally fairly poor.

It depends on the length of the wire. If it's near an odd number of quarter wavelengths long, the radiation resistance between the end and ground will be low, and a good ground system is necessary to get good efficiency. If it's significantly shorter than a quarter wavelength, the resistance is lower yet and a very good system is required. On the other hand, if it's close to an integral number of half wavelengths, the resistance will be high, and you can get by with a very poor ground system -- in many cases just a ground rod -- without sacrificing a significant amount of efficiency.

That's the reason why a half wave antenna works so well on an HT.

My end fed inverted "L" goes up 20 feet and then out 75 feet, with the far end about 25' high. It is fed with a homebrew remote controlled tuner (50' from shack), simple series roller inductor and a parallel capacitor on the output. Ground system is about 6 pieces of various 20 to 30 foot lengths of wire, in a sort of random star shape, buried about 2".
It generally outperformed a dipole I had up with an A/B switch to compare the two. The dipole was 25' up, 65 feet long and fed with ladder line from a link coupled tuner. The dipole was a tad quieter, but the "L" received and transmitted maybe an S unit better.
I've read in more than a few places that you need to get the vertical part as high as possible before it heads on out to the woods.

That does not disagree with anything I said. A lower antenna surrounded
by taller objects is not subject to the same high voltage gradient as
an antenna out in a flat clear field.

> P-noise is observed when there is no rain nor thunderstorms, but plenty

The fact is grounded or ungrounded antennas all behave the very same
way. Ask anyone who has yagis on towers. It is a potential difference
between earth and the atmosphere around the antenna. It isn't the
antenna charging up so much differently than earth. It is the
difference in potential between the antenna and the space around the
antenna.

Remember those old tall mast wooden sailing ships soaked with saltwater
and the fire off the yardarms at night?

You can walk right up to the noise source, and even see the corona at
night. It's very easy to take a FSM with audio monitor or AM receiver
with S meter and walk the roof for strongest noise, and it will
generally take you right to the tallest sharpest object (grounded or
not) on the roof.

The last place you want to be is the tallest antenna on the building.
Get high winds or inclement weather and you will be destined for
noise....grounded antenna or not.

We serviced dozens of repeaters and a few STL or Remote links in the 70's, it was a pattern that repeated.

I have a suggestion. Go to a forum where there are many people with antennas at various heights, like a contesting reflector. Ask people who have similar or identical antennas at various heights on a single tall tower what they observe during high winds, nasty weather, or rain. The very same wind and the very same moisture is impacting all of the antennas, but without fail they will tell you the lower antennas are always much better and the taller antennas are the first to go.

If the P-staic is actually coming from the particles or moisture in air striking the antenna, and if the same basic sample of weather is at all the antennas, why are the upper antennas affected more?

If it is the conductor charging, why do plumber's delight antennas or folded elements with grounded centers have the same noise as insulated elements?

If it is moisture or particles striking the antenna causing the problem, why is an insulated antenna with a single sharp protrusion just as noisey as a bare antenna? Why doesn't the noise follow the pattern of the particle rate, and why does it occur (as you even seemed to say) when there is no actual precipitation?

Since I've always had towers taller than 100 feet, and since I've worked on VHF and UHF systems that had to stay up during storms, I've spent a lot of time looking at this. I've not found anything that points to the antenna charging differently than earth or being struck by charged particles.

73 Tom

The problem with this joke is that the wrench exhists. Handedness in a
wrench is determined by which thumb closes the jaws. Right thumb right
hand wrench, left thumb left handed wrench.

I have a left handed crescent type wrench. Where was it made?
POLAND of course.

Wrench available for inspection.

This is a well known phenomenon in Arizona. What else, besides
charged dust particles, could cause arcing at coax connectors
on a perfectly clear windy day?

Dear Tom:

It appears that two noise mechanisms exist. The two are P-noise and corona noise. A receiver will experience close to white noise in both cases. However, corona noise tends to be accompanied by sudden stops and starts and P-noise starts with a sequence of perceptibly time spaced pops that increase in rate.

If there is corona off of the top of a structure then it is reasonable to expect the antennas most close to the corona will "hear" more noise than the antennas that are farther away (such as below).

It is also to be expected that moving charged particles that are higher above the ground will carry more charge on the average than charged particles that are moving near the ground. Depending on the wind and gradient, I expect that there is a height below which few charged particles are found when higher above ground charged particles are common.

In short: If one can see corona, it will be the dominate noise source. If the gradient with altitude is not sufficient for corona, and weather conditions are such that moving charged particles exist, then out in the open the higher antennas are expected to have more discharges from moving charged particles per second and more noise than experienced by lower antennas.

I have offered an alternative explanation for why, absent corona, higher antennas might well experience more noise.

Actual precipitation (rain, snow, hail) is not needed for P-noise. Moving dust particles can carry charge and become charged. The noise does follow the "pattern of the particle rate." However, as you understand from other work, when the rate becomes high enough compared to the bandwidth of the receiver the result is essentially indistinguishable from white noise. Even with a 400 Hz bandwidth, the onset of P-noise is unique and comprises a sequence of pops that either die away or increase in rate to produce prodigious amounts of noise. I have used a time blanking circuit - noise clipper - and find that it is effective at lower rates. Corona noise does not seem to have the same temporal characteristics.

A moving charged particle is able to discharge into an insulated conductor with aplomb. It is the very-close-to-the-antenna sudden accelerations of charge that produce noise (radio waves). What has shown promise is the use of slightly conductive coverings. The theory is that the amplitude of the pop will be reduced because the rate of charge transfer will be slowed. UV resistant materials that are easy to apply and that are not expensive seem not to exist. Obviously, too much conductivity would be

ineffective.

Absent actual corona, a noise mechanism is contended that comprises the sudden transfer of some or all of the charge on a moving charged particle (that occurs naturally) into an antenna's structure, support or even into insulation around same.

A near optimum, HF, DX, low-noise receiving antenna is a small, horizontal, unturned loop antenna with an amplifier that is mounted on a wood pole having no metal inserts. The pole is some 200 meters from any exposed metal. The coax that runs up the pole to the amplifier is encased in conductive, plastic conduit as is the loop's wire. This antenna has close to a null at the zenith and is omnidirectional in azimuth.

It is contended that what I have observed is not in conflict with what you have observed with corona discharges. 73 Mac N8TT

P.S. Some months ago you asked about V antennas for low HF or MF use involving a 300 foot tower. I found that an interesting topic and did some analysis, which I tried to sent to you. Unfortunately, the E-mail address did not work. My conclusion, was, as well as I am able to remember, the same as yours: at the low frequencies involved, the effort did not have a reasonable pay-back.

At 23, I took a job as a young engineer at a place that had previously been
a gyroscope manufacturer. As the new guy, they asked my to deliver a
briefcase to the boss' office and (you guessed it) there was a spinning gryo
in the briefcase. I got a big surprise when I tried to turn a corner in the
corrider and the briefcase kept going straight ahead! A great 'new guy'
trick.

George
WB3HUH SAYS:

Try DOW Chemical's "Great Stuff ", a "Tripple Expanding Polyurethane
Foam Sealant"
This comes in a paint spray size can and is applied withan attachable
tube.
It sticks to everything, as it goes in as a liquid then expands to fill
even large holes.
It firms up and seals tight. Cable companies around here use it. Even
works well on cinder block

Come on, that sets the bar way too low.

100 wpm CW, and 45 baud RTTY. RTTY is the wave of the future, after all.

And we add a new class called "Extra Extra Read All About It!" where you
have to copy Hellschreiber and PSK31 and copy and whistle 1200 baud packet.

Hi Steve,

This may well be due to its inability to resonate as advertised. This
is not an infrequent complaint.

One compelling contradiction is seen in the description of the antenna
as being 60% of the conventional length; and the illustration of the
antenna built in thirds which would suggest it is 33% of conventional
length. Simple errors such as this lead to massive failures in
expectation.

This leads us to the observation that if you can erect a 1/6th
wavelength vertical, what do you stand to gain with this spaghetti
design that would put it ahead so much further?

> that increase in rate.

Pops are caused by something charging and flashing over. All it takes to eliminate pops is a leak resistance or a leak choke slow enough to keep the antenna from charging.

I've never heard the slow popping noise called P-static by anyone I know, but that doesn't say some people don't call it that.

I have dipole high in the air, and on a clear day with a fair breeze they will knock someone right on their butt if the feeder is unhooked and the antenna allowed to charge. It does that dust or no dust, although nasty weather seems to greatly increase charge rate.

It's easy to see why that happens.

http://www.who.int/peh-emf/publications/3_EHC_232_Sources_and_Exposure.pdf

There is a significant electric field as we increase height even in fair weather. Even though that is a very high impedance field, it doesn't take air movement to charge a high conductor that is well-insulated.

> I have offered an alternative explanation for why, absent corona, higher
> antennas might well experience more noise.

True, but a height change of just a few meters on a building or tower hundreds of meters tall makes a big difference as do sharp compared to blunt points on an antenna.

During a rainstorm, when most people complain about corona, droplets from the very same sources are hitting lower and upper antennas. The noise does NOT follow the pattern or rate of raindrops hitting the antenna, and the upper antenna is always significantly noisier than the lower antenna.

> Actual precipitation (rain, snow, hail) is not needed for
P-noise.

Of course not. It is a voltage gradient problem.

> Moving dust particles can carry charge and become charged. The noise does
> follow the "pattern of the particle rate."

I've never seen it do that. But I'll keep watching for it.

I'm surprised to see Dow with such a product when it competes with Dow
Corning's compounds which are sold under the DAP as well as Dow
Corning names.

The various forms of expandable foam are easier to use, and to me work
far better than the putty and self vulcanizing tape. The Silastic
RTVs (TM) work well, but may be a bear to get out.

What shape is the conductor? If it is a rectangular cross-section, do
a search on the web for "stripline impedance formula" and you should
find what you are looking for. If it's a round wire, diameter d and
symmetrically spaced between two grounded plates separated by h, and if
d < .75h, to a reasonable approximation,

Z0 = 60*ln(4h/pi*d)

(per "Reference Data for Engineers"; my suspicion is that Z0 =
60*cosh^-1(2h/pi*d) is exact for lossless line, but I won't try to
prove it at the moment.) Divide by sqrt(relative dielectric constant)
if the dielectric isn't air or vacuum.

Cheers,
Tom

I just posted suggesting that z0=60*cosh^-1(2h/pi*d) might be the exact
formula for the impedance. That is clearly wrong; don't use it.

Cheers,
Tom

Passing notes in school is how I first learned the code. Took about two
weeks to memorize all the letters so I didn't need a cheat sheet.
I never got caught though. :/

Dunno...1/4 inch dowels sound kind of thin.. I don't know about
metal spreaders. I've never tried it. Might work ok, as long as they
were not a resonant length, or overly coupling to the loop wires.
The resin probably would help stiffen them up a bit. "wood"
Might help, as long as the dowels don't flex enough to shatter the
glass coating, and cause it to crack away.
These problems are a large reason why I don't mess with quads
much. Lots more work, and design considerations with a 3d object
vs a 2d like a yagi. So being the lazy bastard I basically am, I use
almost all yagi's vs quads. So much easier to deal with, being most
of my yagi's are basically one piece with the elements grounded to
the boom. Not much to break or go wrong, unless something falls
on it... :/ On 6m, I use a 3 el yagi , made completely of copper
tubing. It's all one piece, plumbers delight , with the elements
brazed directly to a copper boom. Even the gamma match tube is
3/8 copper tube.

In Arizona, the harder the wind blew on a clear day, the shorter the
length of time between arcs on my coax connector. In a high wind, it
sounded something like the rat-a-tat of a machine gun.

Buyer Beware
I have read all the reviews and I am wondering if they are about the same antenna I purchased. I bought the Cobra junior antenna and followed the directions for installation. The antenna is 50ft in the air in a flat top configuration. When I hooked it up to my radio, it would not tune on segments of certain bands, most noticeably 75/80. I called Joe to get some help and was told that my radio, which has a built in tuner would not accept more than a certain level of SWR and was told to trim the twinlead back 19 feet. I did and while some of the problem was solved, I continued to have problems on 75/80. I emailed Joe to ask for further assistance and was told that the next step was to buy a tuner extender (price $60). Not the answer I wanted to hear. If in fact this kind of problem exists with radios that have built in tuners, prospective buyers should know that in advance. For the cost of the antenna and now the tuner extender, I could have bought a better antenna, which is what I intend to do. I am not pleased with this antenna and would not recommend it especially to someone who has a radio with a built in tuner and intends to use it. Additionaly, the performance on 40 seems to be very good. It seems to under perform on 20. Can't tell on 75/80 because I can't tune the band.

No.
I know a fellow who works in Tech support for a big computer company
who says they get questions likes this all the time.

There are several reasons the product has failed to meet your
expectations.
1- you have likely installed it upside down.
2- Your antenna is defective, the product is not meant to be used with
a defective antenna.
3- Exposure to weather has nullified your warranty.
4- There is an improved replacement product available and you may wish
to upgrade at a special price.

3692. measurements at the antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-08 14:03:05 UTC
From: dansawyeror <dansawyeror@comcast.net>
Message-ID: <hsqdnZGDCqPmsxXZnZ2dnUVZ_oGdnZ2d@comcast.com>
Source record: 58233

Good morning,

This question is: Taking measurements at the antenna and what they mean?

The antenna is a loaded vertical over a set of untuned radials. The feed is 50 Ohm coax with a 1:1 isolation transformer at the antenna. I intend to run a separate coax for measurement purposes to the feed point, stimulate the antenna with a 10 mw signal at the operating frequency, and measure the voltage across the antenna feed and the ground connection.

Will the voltages indicate the relative RF impedance of antenna (including loading coil) versus the ground? If the ground were near perfect the voltage at the feedpoint should be close to zero. These voltages should indicate the power disapation difference between the antenna and the ground.

Thanks,
Dan

Hello, Dan. If we have a quarter wavelength monopole the voltage at the feedpoint is at a minimum but definitely not zero even if we had a perfectly electrically conducting (PEC) ground. If we had a PEC ground and a monopole with no resistive (ohmic) losses then the impedance seen at the feedpoint at resonance would be about 37 ohms resistive. The 37 ohms is the radiation resistance of the antenna. This is where the RF power gets "dissipated" when that power is radiated into free space.

If we use an electrically short antenna and put in say, a loading coil at the feedpoint to resonate the monopole at the desired frequency, we are looking at a radiation resistance of less than 37 ohms. It could be quite small depending on how short the antenna is. If in addition we have finite losses in the monopole structure, loading coil and in the ground/radials, we are measuring a resistance that is the sum of all ohmic losses and radiation resistance. And that's a classic problem - how to separate out all these losses. Without making radiation pattern measurements (to obtain total power radiated) about all you can do is calculate the radiation resistance for a PEC monopole fed against a PEC ground (or use an electromagnetics computation program like NEC to model

the structure.). The measured value less the calculated radiation resistance would reflect the ohmic losses. And you still don't know how much of this is ground loss without knowledge of the other ohmic losses.

There exits another direct measurement technique (Wheeler Cap) for determing antenna efficiency that can be readily applied to antennas in the GHz range but is not practical at HF because of the scaling factor (compare the size of 2.4 GHz yagi or log-periodic with the same type at 14 MHz to put things in perspective). Sincerely,

Altho, these may be easier to use than dux seal,
beware- if the stuff smells like Vinagar (as in
Ascetic acid) , you may be contaminateing your
coax, as is my understanding. And, MOST RTV's
have this feature (contaminateing your coax)!
Not a good situation! as info, Jim NN7K

3699. Re: measurements at the antenna

.....some "seat-of-the-pants" observations (to use an old aviator expression):
To judge the performances of two similar-sized mobile installations, note the value of the shunt-C required across the feed-coax to provide good SWR 50 ohm match (or shunt-L if that option is used).
The more C required (less capacitive reactance), the better [or similarly, the less L (less inductive reactance), the better].
This method of match is actually a version of the classic "L-match" where the mobile whip with its loading coil represents either R in series with Inductance, OR R in series with Capacitance at the feedpoint....depending on whether the loading coil is tuned slightly Below, or Above the resonant frequency. The shunt C (or L) is the third element in the L-Match Equation. (Many readers will already know this)
Since standard antenna equations calculate the actual radiation resistance to be very small in electrically- short mobile antennas, we know that with a perfect ground, and zero-loss mast and coil, the feed-point resistance would be only the radiation resistance of a few ohms, perhaps 2 to 5 (W8JI's web page calculates a 15 ft. antenna on 1.8 MHz to be only 1.22 ohms).
Therefore, if the mobile feedpoint was found to have low SWR 50 ohm match with no shunt element, that would be very bad news.....it would mean that perhaps 2 parts out of 50 were radiated, and the other 48 parts were loss! And of course, here no shunt C (or L) would be required which is the worst news.
Conversely, back to "seat-of-the-pants thinking", the more C (or smaller L) required, the smaller the feed-point impedance had to have been....meaning less loss resistance included at the feedpoint.

Not usually a problem when going through a wall unless the outer insulation
is broken, but RTV is not may favorite for this. Plain old caulk works great
unless you have a big void to fill.

Jimmie already go this one, but if the seal is pretty much out in the
open it will not contaminate the coax jacket. Normally the stuff
won't bother the jacket any way, just don't apply directly to copper
or aluminum braid as the Copper will turn green.

OTOH there are versions available in Silicon that are
non-contaminating and there are also latex/water based versions. Most
of the DAP (TM) (made by DC) is water based although you can specify
Silicon. Once cured there is not a great deal of difference although
there are some.

What good's a hat if it don't keep the antenna dry? I think I'll keep it
though, for some odd reason my SWR's are better.

You seem to be implying more than one measurement, and that with those measurements you can separately determine (radiation resistance + loss resistance in the vertical and coil) and loss resistance in the ground system.

Can you elaborate?

Perhaps a block diagram of your measurement setup might reveal what you are thinking. (If you need a tool for drawing schematics in ascii text, Google for AACircuit. Alternatively, sketch it, scan it and publish it on a web site somewhere... DON'T attach it to your news post.)

3 Killed in Fall From Iowa TV Tower

Jun 01
http://www.breitbart.com/news/2006/06/01/D8HV79B00.html

OAKLAND, Iowa
Three workers fell 1,100 feet Wednesday from an Iowa Public Television tower and died, officials said.

Bill Hayes, director for engineering at IPTV, said the crew was replacing strobe lights when the accident happened.

"They were up fairly high when something went wrong and all three members of the crew fell," Hayes said. "We don't know what the actual cause was."

He said a fourth member of the crew was working on the ground, operating a winch, hoisting parts to the crew.

"We can only assume that the safety equipment failed," said Pottawattamie County Sheriff Jeff Danker.

The men _ ages 57, 27 and 19 _ were pronounced dead at the scene. They worked for Deter Tower Service, of Grimes. Their names weren't immediately released.

A woman answering the phone at Deters said no one was available to talk about the accident. She declined further comment.

>20. Can't tell on 75/80 because I can't tune the band.

That all seems pretty reasonable though the explanation that the
"built in tuner would not accept more than a certain level of SWR" is
not a good way to express the limits of internal tuners, but it is an
explanation that would appeal to those with lesser knowledge.

Well, it looks like you have learned something that many of us know,
that the internal tuner in most radios has quite limited range and is
really for minor trimming of loads to enable the radio to develop
rated power (not to mention poor efficiency on the lowest bands).

Joe advertises honestly that the antenna will need a tuner for
operation on any frequency, perhaps he needs to spell out that what
manufacturers fit into a corner of a transceiver may not be up to the
task.

Frankly, I am wondering why your beef isn't equally with the
transceiver manufacturer for deceiving you with a tuner that isn't up
to the task.

I wonder what "better antenna" you have in mind? The short multiband
HF antenna that has low SWR(50) on all bands (since you have an issue
with tuners) and good performance is the holy grail of HF amateurs

that will provide you with challenge for the years ahead.

To some extent, the residual technical content in amateur radio is mating up system components that are compatible to form a working station.

Message-ID: <W7KdnWZrCYjLIBXZnZ2dnUVZ_rSdnZ2d@comcast.com>
Source record: 58260

No antenna will work across the full 75/80 meter band with low enough VSWR to accommodate all radios. REASON: the bandwidth range +/- 13.3% centered on 3750 KHz to the band edges is excessive. If you cut the antenna for 3.9 MHz it most likely will not load up well below 3.7 MHz. A tuner is required!! PERIOD.

For comparison, the bandwidth range on 20 meters centered on 14.175 is only +/- 2.4%

Don't jump on condemning the antenna too soon. Do some more research and ask more questions regarding 75/80 meters broadband antennas and what "broadband" means.

Be kind folks! You're all correct, but don't bash the guy's head in.

75 and 80 meters is indeed quite a range to cover, especially when it
is actually 85 to 75 meters in wl.

I'd buy a tuner that will handle open wire feed, lose the 4:1 balun,
and get on the air.

Well, I could be wrong, but if one side of the capacitor is on the
inside of the hull, and the other side is the sea water, is not the
motion of the ship going to affect that? ships move up and down quite a

bit, and low draft ones can have a *lot* of that hull out of the water,
and then a few seconds later have water coming over the bow.

Only allow homebrew equipment, and require it to be FCC type accepted
before you can put it on the air. No ICs allowed, no purchased coils or
variable capacitors. Hand make everything.

Mike, did you notice "Mystery's" comment re spending more money on a "tuner extender": "Not the answer I wanted to hear". She/he may be even less interested in the spend on the tuner you describe.

I agree with you that antenna looks worth a try / perseverance, but it will probably need a wider range tuner than commonly fitted internal to transceivers unless you experiment (what's that!) to find a feedline length that the rig/runer accommodates on all bands, or switch feedline lengths.

That's exactly what I use.

130 feet long center fed doublet with 600 ohm open wire tuned feeders.

Tuner is an OLD [30+ years] MURCH UT2000A with a balun.

Runs great on 75/80, 60, 40, 30, 20 meters.

I have used a LP for 20-10 meters. It is currently down as a result of QTH change and limited $$$.

Not really, but I'm not in a mood to argue about stupid shit - anymore. Actually, I could care less. My ham days are few and far in between due to all the ass holes on there ruining it for the rest of us. Maybe you're right..... the code really didn't keep the crud off the radios. Hell, why even have a test at all.

The problem is that antenna is advertised to work all bands.
Unfortunately it doesn't do very well on many bands.

The SWR is "off the scale" on many bands.

Let's see if I can explain this in 200 words or less. :-)

One popular supposition is what Reg indictated, that P-static is caused
by charged droplets hitting the antenna. As each little drop hits the
antenna, it makes a noise from the transfer of charges.

I always thought that also until I started working on antenna systems
on tall towers and buildings. Trying to make them not "noise up" when
the weather was bad turned out to be impossible when the antenna was
near the top of a structure. Shielding the antennas from moisture with
insulation didn't help. The only thing I found that helped was making
another object the tallest sharpest point on the structure, or
insulating or "rounding" the ends.

One of the things I did with a fiberglass Super StationMaster was to
drop a large plastic bucket over the sharp lightning spike at the top,
and the noise all virtually vanished.
Another was placing a copper toilet tank float ball on the top to make
it smooth and round. Worked almost as well as the bucket. So did
putting up a taller mast on a roof away from the VHF or UHF antenna. On
one bank roof with a radio staion's remote brodcast pickup antenna and
two way radio antenna, we just installed a metal flagpole about 50 feet
away (they wouldn't let us have a pipe that protruded above the
roofline as seen from the street, but they accepted and used the
flagpole).

I started listening to my antennas at home, and noticed the same thing.
Lower antennas were always much more immune to what people call
P-static.

Now I'm not saying wind, dust, and moisture blowing across a
well-insulated antenna won't charge it faster, and make an antenna
without a ground path leak arc over some close gap more rapidly.

I'm only saying I never have seen the noise pitch of what people commonly call P-static track the actual number of droplets or dust hitting the antenna, and everything else I've seen indicates the rapid popping that turns to a sizzle and then an almost musical pitch seems to be tied only to charge gradient between the antenna and the surrounding air.

I've been on the top of very tall well-grounded BC towers on days with a stiff stready wind, no dust or rain, and seen a sharp bracket or sharp strand of guyline poking out hissing with corona streamers.

That noise sounds just like what everyone I know calls "P-static".

The same would be true of almost any other doublet-style antenna, I think. Such antennas are often usable on a large number of bands if you have a wide-range transmatch/tuner, but I don't think I know of any which are usable in this way with the limited-matching-range "line flattener" ATUs built into modern solid-state transceivers.

The Cobra Ultralight is only about 60% as long as a normal resonant near-half-wave dipole for 75/80 meters. It's shortened by linear loading. I imagine it has a narrower SWR bandwidth than a simple dipole.

The manufacturer states that a tuner _is_ required. The wording is perhaps somewhat more optimistic about using a transceiver's built-in ATU than is justified, though. I wouldn't plan to use an antenna of this sort without a good external tuner with balanced-output capability (whether intrinsic or via a good current balun).

The original poster might want to consider making a multi-wire (or "fan") dipole. With several sets of wires it'd surely be possible to make one which would tune on 80, 75, 40, and 20 well enough to not need an external tuner... although fitting it into under 80 feet of linear space might prove to be a challenge.

Lots could be wrong here including trying to kibbutz the problem from afar. But it *sounds* like it is a combination of not enough tuner and a "bit" of operator error. The internal tuners simply do not have enough capacity to meet the demands of all-band operation in some cases. I have the Ultralite Senior using the LDG Pro 100 tuner and I simply LOVE this antenna! I know that there is loss on some bands, but any so-called "all-band" antenna is going to be a compromise when compared to a dedicated, resonant antenna. I don't even LIKE tuners, but I have some requirements beyond the Amateur bands including US gov't SHARES and FEMA. I have to quickly move from one band to the other and, in order to do so, I have to accept some loss. However, I am VERY happy and surprised at the overall performance of *my* antenna. Actually, I'm told that it is unusually loud for a 100 watt station on a number of bands and quite readable on others (I don't HAVE to be the loudest thing going to be effective).

I would guess----and that is what it is, a guess------that your internal tuner doesn't have the ability to match this antenna-----AND probably a number of others as well in multi-band service. Or you simply may have overlooked something in the installation---like location or height above ground.

For every 10 users of a product, there's going to be one, perhaps, that is dissatisfied. With the Cobra, the reviews I have read are decidedly in favor of both the Junior AND the Senior Ultralight. You can't win 'em all!

I have the Ultralite Senior and am very happy with it. I have it at 30 feet with the ends dropping down about 15 feet since my lot isn't big enough. I bought it primarily as a local contact antenna since everything else I have is a vertical of one type or another. It turns out to work much better than I expected. I have worked the South Pacific, Europe and Peter One on it with 100 watts. I use the full 100 feet of ladder line it came with to a 4:1 balun through a remote antenna switch and 50 feet of LMR400 coax. Sometimes it receives better than my verticals and it almost always is quieter. In fact that is why I used it for Peter One, I couldn't pick what calls they were coming back to because of the noise on the vertical and half square. My TS-480 internal tuner tunes it on every band, even 6 meters which there are no claims for.

There really isn't a lot of information on the antenna on the page I saw: http://www.k1jek.com/. Many antennas have a spectrum of frequencies and their associated SWR. Knowing my internal tuner can only handle 8:1 but the antenna shows places I am interested in using with 12:1, would help me in my decision to choose the antenna or another. the OP didn't have that information. I know that internal antenna tuners are basically 'fine-tuners' and are very limited compared to external tuners. (at least Kenwood is clear about that in their instruction guides.) I am not pointing a finger at either party, Mystery for not posting the information or some warning nor the OP for not asking. The Mystery page isn't very Corporate looking so one would have to assume some give and take in the purchase by both parties.

Is there any reason the antenna can't be returned for a refund? If not, can it be sold to someone else who is interested?

This is one of life's lessons learned.

I just looked at the review of the antenna from eHam.com:
==========
WA1BSB Rating: 5/5 Apr 24, 2006 14:29

Homemade Ultrilite Senior Time owned: 0 to 3 months

Hi I went and made a homemade Ultrilite I too 3 conductor tv rotor cable 70 ft each side and mounted it to a modified 450 ohm ladderloc at the center I then ran about 50 ft of ladder line down to a 4.1 balun I know the plan calls for 100 ft but I just dint have the spot to coil it up The antenna is in a flat top configuration up between 2 trees about 80 ft up from the balun I ran about 70 ft of RG8X 50 ohm to my 746 Pro it tunes perfect on all bands 10-160 using the radios tuner 1.1 swr Anyhow it works with good signal reports so far on 40 and 20 meter Im looking forward to trying in 75 and 160 Anyhow bottom line whether you make one or buy it its quite the antenna I glad I got one 73s
==========

There are many other reviews about the antennas, both jr and sr.

Maybe there is a better configuration that will work, or he may need the tuner or tuner extender.

Good luck

Buck

I cured the problem by going to 1000v insulation on the
antenna wire. 600v insulation didn't cure the problem.

Buck, how do you know that your tuner can handle (presumably SWR up to) 8:1? Is it a commonly published specification for transceiver internal tuners or external tuners?

The capability of a tuner is much more complex (pardon the pun), but could be mapped for each band to a Smith Chart as an area of input Z that could be transformed to 50 ohms, and then one could plot loss contours to show the acceptable range. What would you do with the information?

Whilst it may be appropriate to specify the tolerance of Z on a nominal 50 ohms antenna with a maximum VSWR in a given frequency range (eg as often done for VHF and UHF antennas), the Cobra does not pretend to present any particular impedance on any particular frequency (remember that user is permitted to use any length of open wire feed operating at high VSWR, so the Z at the tx end of the balun cannot be specified at any frequency).

The Cobra Junior, a 72' long linear loaded dipole, looks interesting in terms of a short antenna for low HF bands with reasonably low losses. I have run some preliminary NEC models and analysed the feed system loss with 25m of W551 ladder line, they look promising. I will build a complete model over HF along the lines of the ones that underly my article on the G5RV feed system at http://www.vk1od.net/G5RV/index.htm . More when it is done in a day or three.

Well, I was envisioning a plate on some part of the hull which always had water on the other side. If the hull on the other side of the plate comes out of the water, you'll of course effectively lose coupling to the water from that part of the plate. But again, if you make the plate large enough so that enough of the plate always has water on the other side of the hull to make a low impedance, the variation won't matter.

Sounds like you might have to make the plate cover a fair portion of the hull to insure that there's always water on the other side of some of it. If the entire hull comes out of the water, just remember to say "mayday" really quick every time the hull hits the water. Other than that, seems to me you'll probably be too busy to be playing with the radio anyway.

Nah, not all of "us" or "you" in the case of your statement. I'm just saying a lot of crap is going on - on the bands today and its not worth even earning a ticket for - anymore. Ham radio and yes, even CB - used to be respectable at one time. How times change. Its hardly worth turning on the radio anymore. Especially on say 10 and 80 meters. But back to "your" statement, there are still "many" decent operators on both the Ham AND CB bands - out there. Ya just got to pick through the rubble to find them sometimes.

And NO, I"m not the "ONLY" "TRUE" Operator left........ Don't put words in my mouth, I certainly didn't place myself on any pedestal. Again - there are LOTS of decent operators out there. I didn't say "ALL" were bad - but there are - you have to admit - quite a few bad ones. Its gotten worse in the past few years.

I found 1/4 inch fiberglass a little flimsy for a 6 meter quad but workable,
3/8ths was much better. next time I build one it will probably be 1/2 inch
fiberglass.

Be careful when working with fiberglass - after a while it tends to flake
and you could get the fiberglass in your hands, etc. - wear gloves.

Here's what my IC-756PRO manual says about its internal
tuner: "*Matching impedance range: HF bands, 16.7 to 150
ohms unbalanced (Less than VSWR 3:1)"

In the manuals or specifications of most radios I have looked at with internal tuners, they say somewhere what the tuner can match. The Kenwood TS440SAT had in its instructions somewhere that it could match antennas with SWR up to 10:1 (which seems to be typical of most internal tuners on radios.) I have read the specs of many rigs including Yaesu, Kenwood and Icom. I can't say which have the specs and which don't, but I remember reading the specs many times for many radios.

I would read the radio specs, check my antenna and if the antenna matched, it matched, if not, I would use an external tuner, adjust the antenna, replace the antenna or repair the radio if necessary.

I saw NO specifications on the antenna related to resonance when I looked (the link is posted on an earlier posting.) This leads me to believe that the antenna is made by a hobbyist rather than a professional corporation. This isn't necessarily bad, but it would mean I would look into it further before buying. Reading the reviews in eHam, etc, which I believe pointed to a good antenna not addressing

your specific problem. However, having as much information as I have, I would have done what the first reviewer on eHam did. I would build my own and test it.

I will be glad to look at that. I hope it helps the OP.

>Owen

Thanks,

When looking at antennas, I first look at all the information available from the manufacturer, then I look for reviews such as at eham, and I might bring it up for question here and at similar forums.

The antenna in question has no specifications or promises, per se, except for the claim that one can tune it to all the bands. This claim is reinforced by the reviews on eHam.com. As I said earlier, I wouldn't buy it, I would build it. I like doing that. :) If I were to purchase it and had an internal tuner in the rig, I would ask the maker or seller of the antenna if it is expected to work on my particular radio. He might inform me that the antenna might not work on some internal tuners and I would be better informed before I purchase.

Of course, the OP apparently doesn't have this information, or didn't read it about his particular rig. Then again, there are very many external factors that could affect the antenna.

I recently helped someone connect an 80 meter antenna to a TS-440 SAT which has an internal tuner. When we tested it in one position, it worked perfectly. However, when we added 6 feet of coax to move the radio and it suddenly tuned everywhere in the mars 4 mhz band except the area around which he meets in his net. We had to trim the antenna to make it match. Strange, but true.

I didn't analyze the whys and wherefors, but we did get the man operating successfully, which was the purpose of our visit.

Well, I have to get ready for that four letter word forbidden on local repeaters here.

73 for now.

Sounds like time for Cecil to join in. I know his system uses
switchable lengths of twinlead, but perhaps he might have something to
offer here in a one length feedline system.

Yes, the Ultralite Senior is quite effective! Mine is at 60 feet at the
apex and the "Vee" droops down to about 20 or so. I get pretty nice signal
reports both from local and afar. You can't always win 'em all, but when an
antenna works *reasonably* well most anywhere you work, a fella can't ask
for much more! And I am perfectly happy with mine.

AH! HA! We can dress our daughters in poodle skirts and drive to the
testing session in our brand-new 1961
Chevrolet Impala Sport Sedan!

Time marches on, boys, and as we age into crotchety old men (Gosh, I hope I
don't do the "crotchety" part!), we long for the 'good old days'---whatever
THAT was.
Some of us cling desperately to Hallicrafters receivers and Globe King
transmitters we bought when our hair was dark and full, and loathe the new
'mini' transceivers (likely because we are befuddled by the menus), and we
want Amateur Radio to stay exactly the same as it was *just* for us! We fuss
at the newer automobiles and say "I wish they made 'em the way they used
to". I DON'T!
They are actually BETTER than Dad's '65 Galaxie, last longer and run better.
(Try to tell that to the past-dwelling guys who cling frantically to their
youth, and they'll lecture you on the virtues of a '56 Chevy AND the
51J2...not that the older stuff isn't "good", just part of the PAST! Which
we, BTW, should remember as a basis for advancing into the future.

I don't really like it that CW is going away, but it WILL go away so far as
necessity goes same way we don't commute to work in our '56 Fairlane. So we
ADAPT to change instead of vainly clinging to the way WE think it should
stay forever and a day. When we are dead and gone, the world will be vastly
different than we would've remembered it!

Things are slow here at the GED office today so I modeled
the Cobra-Jr and Cobra-Sr. The Cobra-Jr suffers from
feedpoint impedance problems similar to a G5RV used on
75m. The feedpoint impedance on 3.7 MHz is about
16.5 + j459 ohms giving a 450 ohm SWR of 56:1.

For my variable feedline method to work with 450 ohm line,
the SWR must fall between 4.5:1 and 18:1. A dipole that is
1/2WL on the lowest frequency of operation usually meets
that requirement. The G5RV length doesn't and the Cobra-Jr
doesn't.

One thing interesting about the Cobra-Jr is that if it is
made 62 feet long instead of 73 feet long, it becomes
resonant around 3.85 MHz with a feedpoint impedance of
about 16 ohms. That's an SWR of only about 3:1 on coax.
or ~1.3:1 using a 1:4 balun. That's a half size antenna
for 75m that is only about 1.5 dB down from a full size
1/2WL dipole.

3760. Sinusoidal Antenna Currents

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-09 16:13:19 UTC
From: Cecil Moore <mycall@hotmail.com>
Message-ID: <z6hig.113516$dW3.81939@newssvr21.news.prodigy.com>
Source record: 58201

Here's a quote from Kraus' "Antennas For All Applications"
3rd Edition, page 177, section 6-4:

"The Thin Linear Antenna - In this section
expressions for the far-field patterns of thin linear
antennas will be developed. It is assumed that the antennas
are symmetrically fed at the center by a balanced two-wire
transmission line. The antennas may be of any length, but
it is assumed that the current distribution is SINUSOIDAL.
Current-distribution measurements indicate that this is a GOOD
ASSUMPTION provided that the antenna is thin, i.e., when the
conductor diameter is less than, say, lamda/100. Thus, the
sinusoidal current distribution approximates the natural
distribution on thin antennas." Emphasis mine.

So Kraus gives us permission to treat the currents on a
dipole as sinusoidal as long as the diameter of the element
is less than 4 inches on 30 MHz or less than 40 inches on
3 MHz. So virtually all HF dipoles are thin-wire antennas.

And since the current distribution is assumed sinusoidal, the
arc-cosine function will yield the number of degrees a point
is away from a current maximum point, e.g. the phase information
for the forward traveling wave.

Yeah, and I've had these two left handed pipe wrenches around for
years. This southpaw found them indispensable on galvanized, but can't
seem to get them to work on copper pipe.

> and then a few seconds later have water coming over the bow.

We are not talking about 16 foot dingys here, we are talking about vessels mostly over 30 feet in length, and usually with over 3 or 4 feet of draft. Just how much coupling to the seawater you have is a function of area of the inside capacitive plate, and the distance between it and the seawater. If the dielectric distance is a few inches, and the inside plate is below the waterline, then coupling will not change apperciably, just because the water is sloshing around a bit on the hull. Even if a bit of the surface area of the inside plate did come above the waterline for a little while, say on a hard tack in a sail rig, the coupling still wouldn't be appreciably reduced by loosing 5% of the surface area. These are not really valid problems that one sees, when operating MF/HF Marine Radios that have a decent, Low Impedance RF Ground System installed in the first place. doing it right the first time solves a lot of ills down the road, and skimping on the RF Ground, is a presciption for disaster.

3765. coverage analysis using TIREM

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-09 19:57:01 UTC
From: MRW <mr.whatever@gmail.com>
Message-ID: <1149883021.281768.106120@y43g2000cwc.googlegroups.com>
Source record: 58207

Howdy... I was playing around with this propagation software on my friend's laptop. I had a coverage simulation running on 98.1MHz using a vertically polarized dipole. I decided to pick a location where they have rolling plains to be as close to an ideal freespace calculation. Here is my spec:

transmitter location: +41.083N, -98.395W
antenna height: 80 to 120 ft
antenna type: dipole (I decided to use 0dB for my gain just for reference)
polarization: vertical
terrain data: DTED
propagation model: TIREM
frequency: 98.1MHz
system losses: 5dB
TX power: 50W

So I came up with the following data:

antenna height: 80 ft
distance where power level is -110dBW: 13.3 miles

antenna height: 100 ft
distance where power level is -110dBW: 12.32 miles

antenna height: 120 ft
distance where power level is -110dBW: 13.3 miles

Why did my signal level drop at 100 ft?

i believe in this description he is refering to the current distribution of the standing wave. that is, the classical sine curve that shows a maximum at the feedpoint of the 1/2 wave dipole and zeros at the ends. in this case the shape of the curve is a function of the sin or cos of the distance from the feedpoint divided by the leg length times pi/2 or 90 degrees, which ever you prefer.

however, that is not the phase of the forward traveling wave, that is the envelope of the sum of the forward and reverse waves... or the standing wave. the phase of a traveling wave is added to the omega*t value in the sin(wt+p) representation, but in a distributed system must be referenced not only to a time but also the location. or in simpler terms you can reference it to the time that the current crosses zero at a given point in the forward traveling wave. to get rid of the time dependence you must add the foward and reflected waves to get the standing wave, then you can make the classical sunusoidal dipole current plot.

I'd have to look at the antenna in my own antenna modeling program,
which I don't have right now to be sure of this, but I'd guess it has
something to do with the antenna being an integer number of wavelengths
above ground. 100 feet is almost exactly 10 wavelengths at 98.1MHz.

Do you have an antenna program that lets you look at the elevation
pattern of the antenna? My guess is that at 10 wavelengths high,
there's more energy in higher angle lobes which I would expect that a
line-of-sight coverage prediction program doesn't report anything
about.

Exactly, and that is the number of degrees by which the forward
traveling wave lags the source wave and therefore is the phase
angle of the forward traveling wave reference to the source wave.

> however, that is not the phase of the forward traveling wave, ...

Of course it is, referenced to a source phase angle of zero.
Assuming the source phase reference is zero degrees, the phase
of the forward traveling wave is related to the distance from
the source (modified by the velocity factor). That's just simple
physics.

Given the source current is 1.0 amps at zero degrees, the
standing wave current 1/2 way to the end of the antenna element
will be 0.707 amps at zero degrees. Arc-cos(0.707) = -45 degrees.
That's the phase angle of the forward current at that point since
it lags the source current. Hint: There are very close to 90 degrees
of antenna between the source and the end of a 1/2WL dipole since
it is 1/4 wavelength. Remember 360/4 = 90 degrees.

When I reached my first duty assignment in the USAF I was sent on a fools errand to get 1000 yards of flight line. When I got to the place I was suppose to pick it up I told the guys there that I knew what flightline was but I had an idea for a joke on the guy that sent me down there.They were very happy to help. We went out back of the base and loaded up a truck with rubble from flightline construction then took it back and put it the POV pickup of they guy who had sent me out. When I went back to the shop I told him I had the flightline but didnt think I had the thousand yards he had requested. This got him and everyone else in the shop curious and they all wanted to see what I had brought back. Thats when I told him to go look in the back of his pickup.

Where are you observing resonance?

I created a model with ~73' length that does resonate (low Z) at the
dipole centre around 3.6MHz. Other factors affect resonance a little,
but you may want to check your model to see it is laid out properly
and connected up properly.

Take 2 antennas on 6m - one is an inverted V and the
other a 3el quad. Both are mounted at near the same
height and fed with about the same length of coax.

Is it normal for the quad to be quieter?

Signals are louder on the quad - it's just the background
noise is higher on the V.

Just curious.....

We had a second station in the 160 meter CQWW contest moving up and down the band working people. That staion just used a 160 meter dipole at 60 or 70 feet. I was amazed they could work anyone they called and got through pileups very quickly, often on one call.

Of course when I compare that antenna to the main transmitting antennas, it is typically 10-20 db weaker. Sometimes it is 40-50dB weaker.

Of course I can work anything I can hear with my mobile using a 10 foot tall antenna. I've worked Europe on SSB 160 meters and Australia several times on CW, and I've worked all over the world on 80 and 75 meters. I have even worked Australia longpath on 40 meters in the late aftenoon (VK6VZ) while sitting in rush hour traffic, and I've done that more than once!

All of the above is absolutely true, and all of the above is totally meaningless when it comes to quantifying how well an antenna actually works. The only meaningful part is we are happy with the contacts, and if I didn't have a better antenna I'd swear my 70 foot high 160 dipole or my mobile antennas were the best thing on the planet.

Noise almost always arrives from multiple directions and from different directions than the desired signal.

It is normal for ANY antenna to be quieter when it is more directional. As a matter of fact, it is expected that S/N ratio is a direct function of directivity of the antenna as long as the noise and signal are not coming from the same direction.

To answer your question, it would be very abnormal if your quad (or Yagi or any other directional antenna) was noisier than a broad pattern antenna like your Inverted Vee dipole.

By the way, a real Inverted V is a longwire array fed at one end. I'm assuming you really have an Inverted Vee dipole, and not a true Inverted V.

It isn't going away any more than tubes are going away or crystal-controlled oscillators are going away. Those of us who wish to use them are free to do so (and this freedom will probably continue for a long time).

Railroad fans admire steam locomotives, car buffs fawn over a Model T and old men love their old wives. But in each case, the object of their affection is, like Morse Code, past its peak of popularity and practicality. Yes, learn Morse, use Morse, even love Morse -- but for crying out loud, stop pretending it's the be-all-end-all of ham radio -- because it isn't.

Yes, yes, yes -- I know Morse Code will get through when other modes fail. I've heard it a hundred times, so it must be true. However, this doleful situation almost never presents itself. If this were a practical view of the world, then we should all buy Army tanks, the better to navigate the rubble of a natural disaster when all other means of transportation are unavailable. (Not a perfect metaphor; work with me, OK?)

Although I have no objection to YOU using Morse Code, I personally resent it because I can't learn it. I've wasted countless hours trying and it just doesn't happen for me. Too bad, so sad. But there are rays of sunshine. The FCC may just lift the requirement off my shoulders before another year passes and in the meantime, maybe I'll rack up more club FD points on UHF/VHF voice than the HF guys on all modes combined. I did it in both 2004 and 2005.

Well, the antenna system looks promising on some bands, but not
others. Draft article is at http://www.vk1od.net/cobra , constructive
comments appreciated.

The article includes a link to a graph of the modelled system losses
for the Cobra Senior, but it looks pretty uninteresting with ~9dB of
system loss at 160m... there is no shortage of poor performing
antennas on 160m.

OK, let h=2*h1 and d= wire diameter
Then, for p/h < 0,75
Zo = (138/sqrt(e))*log10(4h/(pi*d))
where pi = 3.14159.... and e = 2.7183...

Others have reported the same.

If you have RFI, either on transmit or on receive, then a feedline choke ("current balun") at the antenna feedpoint would be the first thing to try. It's easy to install - but even easier if you install it at the same time as the antenna.

"Prevention is better than cure" is a very good principle.

A tuner extender is about worthless. It is an autotransformer. Nearly every auto tuner has more impedance range than the ferrite core autotransformer used to extend the tuner.

The problem really is the Cobra does NOT have resonances at the points that are claimed, so impedance is off the scales on some Ham bands.

I measured a Cobra that was supposed to hit 80, and it missed by a few MHz. A person would be much better off doing something else, although I'm sure with a good tuner contacts could be made on any band.

After all.... I can work Europe on 160 SSB and VK's on CW with my mobile antenna, and it is less than 1% efficient and that is on 160!!

Why would anyone wanting the antenna to radiate and not the feedline
ever make a direct connection without some planning???

It seems foolish to go through the effort of puting up an antenna and
not doing something so simple in advance rather than waiting for
problems.

What are SWR's? Does your antenna have multiple standing wave ratios?
Were they sick? Did they have MPD? Do you SWR's look in the mirror each
morning and say "well, who are we going to be today?"

Does the standing wave ratio own something called "are better"?

Are SWR's related to 73's, and if so does the hat help 73's also? Is
your antenna still a fertile female that gets wet whenever a large
capacitance hat climbs on top?

A local school had "Spelling Award's Day" on a sign out front. When I
saw a pamphlet, it said "Selling Awards' Day".

Maybe it was award's for selling extra 's as a school project
"SWR's" and "73's" , or should I s'ay award's for s'ellin extras'
s'sses ?

73's and Happy SWR's to all,

The number that TIREM calculates will depend among other things on the vector sum of the direct and ground-reflected or diffracted rays for the model conditions -- which are a function of ERP, antenna height, path length, and the terrain profile along that radial. Probably the combination of these at the 100 ft elevation of the transmit antenna was responsible for the result you saw.

If you get a chance, check several other radials to see what happens.

An FM receiver needs a certain minimum level of r-f voltage at its antenna input terminals to meet its noise performance specification. Stereo mode requires more r-f than monaural, for the same S/N at the receiver output.

No doubt if you use an antenna capable of giving your receiver the r-f input signal it needs, your noise level will drop to inaudibility (at least with normal programming).

Not to mention that noise is normally a phenonmen
of the Vertical Plane (which , depending on how
steep your inverted "vee" is, will contain some
vertical component, while the yagi/quad is
Horizontal to the plane. This has been a factor
on vhf for years, as noise levels tend to peak
at 6 meters (50 MHz). The MAIN reason that F.M.
is Vertical polarized is that for mobiles, it is
easy to construct an omni-directional antenna.
Most vhf manuals detail this effect! Jim NN7K

For beams, the desired radiation pattern is usually
more important than minimum SWR. Using EZNEC, I've
seen a 4:1 SWR yield the desired pattern where
at the minimum 1.5:1 SWR point the F:B ratio was
terrible.

Quads are a lot less noisy than Yagis when the wind
is blowing in the Arizona desert. Quads have a DC
short across the feedpoint that reduces noise from
static buildup.

In addition to Richard's comments, many higher quality FM receivers employ a
"muting" switch on the front panel.
The Kenwood KT-8300 has 2 selectable mute settings in addition to off
while the NAD 4020B has a single setting with an on/off switch.

For years we called that 'white' noise or 'background' noise.

Now, with a full quieting signal, >20 uv, if it's being heard on FM I'd suspect the discriminator or limiter circuits. I'd start looking at the limiter.

Ahem. In your formula, e is the relative dielectric constant of the dielectric between the planes and surrounding the wire, NOT the base of natural logarithms. And I assume that "p/h < 0,75" should be d/h < 0,75. Then it's equivalent to what I posted earlier.

Cheers,
Tom

Dave,

If you've never heard of 'pink' noise, then you're probably not a student of noise.

In noise parlance, 'white' noise is the term that is usually used for non-bandlimited noise (ie, 'broadband noise'). "Pink' noise, on the other hand, is a term used to refer to bandlimited noise. In practice, anything that comes out of the audio channel of a communications receiver is really 'pink' noise, as the bandwidth is limited to a few KHz. On the other hand, the noise that is incident at the antenna or generated in the front-end is much broader in bandwidth and is more deserving of the term 'white' noise.

I did model this antenna with EZNEC but I forgot to take
into account the fact that the wire used is insulated. I think
that screwed up the resulting antenna. Maybe? Would an
insulating jacket reduce the VF of the wire? I've accounted
for everything else, wire gauge/loss, ant height, type of
ground, etc.

Source record: 58092

White noise has a uniformly distributed power spectrum.

Pink noise has a spectrum which smoothly decreases in power with
increasing frequency. That is, power is concentrated at the low
frequency (or red) end of the spectrum.

In a narrow band of audio frequencies they both sound the same. There
is no detectable difference between the high and low frequency ends of
the narrow band.

The two terms are usually applied to very wideband communications
systems, ie., from VLF to UHF.

Purely randomly generated noise is described as white. Its
statistical properties are defined as having a Gaussian amplitude
distribution. It is by far the most common natural source of noise.

See Google for the Gaussian Distribution or Function.

It is simple enough : Exp(- x*x)).

It occurs throughout Science, Engineering, Medicine, Economics,
Statistics and in all facets of human activities, life on this Planet
and dead materials.

Even politics. It may be said that Blair and Bush lie in the extreme
tail of the Gaussian Distribution. Which of the two tails I have been
unable to fathom.

Reg.

Methinks your leg was being pulled.

The SWR with the apostrophe s is a grammatical error. The apostrophe s indicates that the SWR is possessive, that the SWR owns something; or, that the SWR is doing something. The apostrophe s is not plural!!

The plural, multiple, SWR is denoted SWRs.

too bad, so sad, indeed

You know, as long as there are effective band plans allowing for CW,
data, voice, etc., I really don't care what the FCC does. I learned
Morse code as a teenager so I really can't relate to the impossibility
of the task. Don't know how THIS old dog would do with a new trick.
All I can say is CW is very enjoyable to me and deserves a prominent
place within the bands.

OK now I'm really starting to think I should prune my reflector
and director - here's a quote from the ARRL Antenna Book
2003, page 12-4:

"In practice, it has been found that the length around the loop
should be approximately 3.5% greater than the self-resonant
length if the element is a reflector, and about 3.0% shorter than
the self-resonant length if the parasitic element is a director."

I built my 6m quad with a 240.64" driven element which I had
to trim 6" to get the SWR where I wanted it (low end of 50mhz).

My reflector is 246.64" and my director is 233.41".

Help? Do I trim or not? I have done some tests with the ant
up and I'm noticing my F/B ratio is not as good as the EZNEC
model predicted (30.62 db predicted, I'm seeing maybe 2-3db)

Ken KG0WX
Always learning.....

The Handbook means the self-resonant frequency with no other elements around. They do NOT mean compared to the size of the driven element.

A driven element can move higher or lower in frequency as you add other elements, depending on the tuning of the other elements.

I usually do all my F/B tuning first, and then SWR last. By the way, I HOPE you have a balun at the feedpoint. Without a balun at the feedpoint, the F/B can be seriously diminished.

I have about 8 turns of coax at the feedpoint. Is that good enough or
do I need a 1:1 balun also?

Thanks for the help!

Virtually all Yagi's have dc paths to discharge the elements.

The primary reason a quad is quiter is it has no sharp protruding ends
that are sticking way out in the air.

As a matter of fact if you research the quad, it was initially used to
eliminate corona at radio station HCJB.

Try this test, wire a small 2.5 MHh RF choke across your antenna and
check the before and after noise levels. They will not change.

Yes, most of us have been bitten by that bug in our
thinking. Exactly the same thing happened to me with
"My Favorite Loop Antenna" on my web page. If I remember
correctly, the insulated effect is around 3% on VF.

On the contrary, the plural of the letter A is A's. The plural
of the number 3 is 3's. It's not too much of a stretch to assume
that the plural of SWR is SWR's.

From Webster's: "apostrophe - a make used to indicate ... the
plural of letters or figures."

Yep, designed by my distant cousin, BTW.

> Try this test, wire a small 2.5 MHh RF choke across your antenna and
> check the before and after noise levels. They will not change.

Obviously a false statement based on limited knowledge and
experience. Any ham living around Phoenix will be glad to
enlighten you.

That's exactly how I eliminated the noise and arcing on my
first bare-wire G5RV installed in Arizona. I didn't measure
the change in noise level but it went from arcing at the coax
connector to not arcing at the coax connector which was
acceptable to me.

If the driven element on a Yagi is an uninsulated dipole, it
is susceptible to wind driven noise on the driven element just
like my G5RV was.

Just because you have never experienced that type of noise in
Georgia doesn't mean it doesn't exist in Arizona. I dare say
you haven't experienced a lot of things that exist in reality.
Mary G. comes to mind. :-)

Thanks for the info, Cecil - I just got back in the shack from trimming all 3 elements. The SWR is now pretty close to what EZNEC predicted. I can't tell if I've got any pattern on SSB because 6 is wide open and full of contesters. There is a beacon 80 miles away that I'm hearing and I'll try to see what kind of pattern I have receiving that.

When did you do that test?

When did you compare other antennas, like noise on plummer's delight antennas?

How many Yagi's have floating driven elements without ground paths?

=====================================

Indeed, it is often referred to by statisticians as the "Normal" statistical distribution function. Why such a simple function should be so universal is a matter for conjecture.

Unfortunately, elementary statistics and tossing of dice is a much neglected subject in our schools. Japanese, Chinese, Korean, Russian, Indian, Central Asian, even Iraqian, Iranian and Palastinian school children are probably better educated.

The whole of human life is just a matter of chance. I consider myself to have been very lucky.

Please excuse my computerised wanderings!

On the contrary, the plural of the letter A is A's. The plural
of the number 3 is 3's. It's not too much of a stretch to assume
that the plural of SWR is SWR's.

From Webster's: "apostrophe - a make used to indicate ... the
plural of letters or figures."

You're both over-generalizing. In VHF/UHF/SHF yagi construction it's quite common to find driven elements connected to the boom or floating. The same choice or a different choice may be made for the parasitic elements.

There are many different reasons for these choices, including:
* size of elements and boom
* mechanical strength requirements
* effect of boom on element resonance (depends on mounting method)
* long-term effect stability of element resonance
* feed impedance of driven element (affects choice of feed method)
* number of elements involved
* perceived or actual effects of "static".

This makes the choices quite complex, and makes generalization impossible. Quote an example, and someone else will quote you a counter-example.

Just one other thing: PLEASE let's not talk about elements being "grounded", way up there at the top of a tower.

The entire topic and people's reactions about precepitation noise is fascinating.

People actually seem to think the little particles voving through the air charge the antenna to a different potential than the air around the antenna, and that a "dc" path to earth or "dc" path around an element somehow magically stops RF noise.

Certainly it is possible for a conductor very well insulated from earth to charge to the potential of the static field around the antenna, and flash over to "ground" through some path that breaks down. Of course only a fool would have equipment that allows that to happen while large antennas are being used or connected. This is an entirely different thing than the corona discharge that makes what people typically call "P-static".

> Cecil Moore wrote:
>> Obviously a false statement based on limited knowledge and
>> experience.
>
> When did you do that test?

Around 1990 to cure the arcing at the coax connector
during clear-sky high-wind conditions in the Arizona
desert. When I got rid of the coax and used ladder-line
all the way to the tuner, I discovered that the 4:1 balun
in the MFJ tuner accomplished the same anti-arcing function
so hams using ordinary 4:1 voltage baluns are equalizing
that charge before it can arc.

> When did you compare other antennas, like noise on plummer's delight
> antennas?

The noise was the arcing of the coax connector at the input
to my IC-745 which woke me up at night and scorched my rug
after I disconnected it and laid it on the floor. Seems
obvious that going from arcing to not arcing changes the
noise level. I was afraid to turn the transceiver on during
the arcing process. If I had known I was ever going to have
this conversation with a doubting Thomas, I would have hung
an o'scope on it. The condition is well known to most desert
hams but I had just moved there from Silicon Valley. I never
experienced the condition in Silicon Valley or East Texas.

Installing the RF choke across the antenna feedpoint
cured the problem. I'm not talking about plumber's delight
antennas here. I am discussing Yagis and other antennas
whose driven elements are center-fed dipoles where there
is no DC path between the driven elements.

> How many Yagi's have floating driven elements without ground paths?

It only takes one red car to disprove the assertion
that all cars are white.

All the Yagis that I have built used isolated dipole
elements and it only takes one to demonstrate the clear-
sky high-wind noise problems in the Arizona desert. Every
Arizona desert ham running bare isolated HF elements with

no DC path to ground will encounter the problem sooner or later. The problem has been discussed here on this newsgroup in the past, possibly while you weren't reading it. As I remember, one ham solved the problem with a 10K 3 watt carbon resistor across the feedpoint.

It seems apparent to me that the problem occurs in very low humidity conditions. That would include dust and dry-air snow. And the dust doesn't have to be visible to the naked eye. I've seen it happen with clear-sky and seemingly clear-air conditions with high winds and low humidity. I suspect dust/pollen particles too small to see still carry a dry-air charge.

That definition agrees with what I learned in English
class 50+ years ago. The plural of a number uses an
apostrophe. So 73's would indeed be the plural of 73
as in "many best regards". It's no stretch to assume
that the plural of SWR would be SWR's.

Incidentally, I have an obvious typo in the definition
that the spell-checker didn't catch. Should have been:

"apostrophe - a mark used to indicate ... the plural of
letters or figures."

I have a "Webster's New Universal Unabridged Dictionary"
which contains a "Basic Manual of Style" in the back.
Here's what it says for "Apostrophe: ... 3. To form the
plurals of letters or figures add an apostrophe and an s."
That's seems to be prescriptive.

Would a "Basic Manual of Style" change your mind?

I have a "Webster's New Universal Unabridged Dictionary"
which contains a "Basic Manual of Style" in the back.
Here's what it says for "Apostrophe: 1. ... 2. ... 3. To
form the plurals of letters or figures add an apostrophe
and an s. ..."

It does say that a few people object to number 3. As in
many other areas of the English language, the context of
the use of the apostrophe determines its function:

1. to replace missing letters,
2. possessive,
3. plurals of letters or numbers.

P.S. The better educated posters avoid violating the
attribution rules for newsgroups.

Please don't accuse people of believing in magic until you
understand the physics involved.

There's no magic involved. Dry-air dust and snow particles
certainly can transfer a charge to an uninsulated wire in
the air. It is simple physics to realize that when a highly
charged particle touches a conductor, the charges between
the two objects will be equalized. It would be magic if the
particle and the wire did NOT equalize their charges by
transferring excess differential charge when they come
into contact.

Given a dipole where one element has a DC path to ground
and the other element is floating with respect to ground,
it is reasonable to expect the charge between the two
elements to be different and they often are. The difference
in charge will build up to the point where the smallest gap
between the two conductors arcs. In my configuration in
the Arizona desert, that gap existed at the coax connector
at the transceiver and it did indeed arc badly. It woke me
up and scorched my rug after I disconnected it from my
transceiver. The arc was bright enough to light up the
room and certainly caused RF noise. The wind was blowing
around 30 mph and there wasn't a cloud in the sky.

Given an extreme relative charge between the element with
a DC path to ground and the element without a DC path to
ground, anything that will bleed off that charge will cure
the problem. An RF choke works. A 4:1 voltage balun works.
A resistor works.

Perhaps we can convince a desert ham to hang an o'scope
on a clear-sky, dry-air system on a windy day and report
back here with some results. Many other hams have reported
the same thing during a dry-air snow storm.

> somehow magically stops RF noise.

Let's say we have the following bare-wire dipole system
link coupled to the receiver (in fixed font).

```
|
| dipole element A link coupled
| -////-
+-------------------------------------------------///////--+
|
+-----------------------------------------------------------+
|
| dipole element B
|
```

Let's assume one highly charged particle hits dipole element
A and transfers half of its charge. Element A will then have
an excess charge one half of which will migrate through the
link while equalizing the charge between element A and element
B. That charge migration/equalization no doubt results in an
RF noise pulse.

This experiment can easily be performed by anyone.
Rub one's leather soles on a wool carpet, touch one side of
the dipole, and listen for noise in the receiver. Guaranteed,
it will be there.

Now multiply the above by millions of charged particles
randomly encountering the bare-wire dipole. The charge on
each side of the dipole will never be exactly equal. Thus,
continuous broad-band noise will be continuously transferred
through the link as long as the particles are transferring
charge to the antenna. That's what some hams are hearing
during dry-air dust and snow conditions. Some have even reported
being able to hear individual particle collisions from large
snowflakes.

as others have noted: Arecibo, HAARP, SW curtain arrays.

for 20 meters, there have been 48 element Yagi stacks.

i'm not aware of any amateur curtain arrays, but several people have modeled these before. you need tall towers, obviously. see the cebik site if you are interested in how curtains work.

it would be pretty easy to set a record for ham HF gain using Yagis, rhombics, or curtain array. whether you'd get good performance and a useable beamwidth is another matter.

Thank you all for your replys, they were all interesting.

The first set of test measurements were taken on a 2-meter loaded vertical. Two voltage readings were taken via a high impedance scope probe, one at the feedpoint of the coax center connection, and the other from the connection of the coax shield to the antenna ground. In this case the ground is a simple raised metal 1/4 inch screen mesh about 10 square feet.

The antenna was tuned to resonance. The relative voltage readings were the center conductor was 2x the ground reading. I do not have a way to measure current at the base at this time.

However looking ahead, with power = iv would this imply about 2 times the energy is being radiated from the vertical element as through the base?

Thanks Dan - kb0qil

What frequency?

>Two
>voltage readings were taken via a high impedance scope probe,

This sounds like a set up to imagining better results than can be
obtained. Scope probes are not magic detectors and what you describe,
following, sounds like wishing:

>one at the
>feedpoint of the coax center connection, and the other from the connection of
>the coax shield to the antenna ground.

A Scope probe has two (2) connections, and at any frequency in HF and
above, their separation is going to have a significant impact on
measurement. You never say just where the second lead goes for each
voltage reading. If you made NO second connection (and just left that
at up to the far end of the probe's connection to a mystery box) then
you have definitely confirmed that dream is in Technicolor and
surround-sound.

>In this case the ground is a simple
>raised metal 1/4 inch screen mesh about 10 square feet.

This is rather less than fully descriptive as 10 square feet can take
many forms.

>The antenna was tuned to resonance. The relative voltage readings were the
>center conductor was 2x the ground reading. I do not have a way to measure
>current at the base at this time.

And this raises one particularly pointed question:
Ground was at what potential with respect to ground?

>However looking ahead, with power = iv would this imply about 2 times the energy
>is being radiated from the vertical element as through the base?

Hi Dan,

There is far too much ambiguity in what you post. What is posted is
fraught with conceptual problems. Basically, you've managed to obtain
two voltages whose relationship is meaningless at best. I'm sure the
potentials exist, but they define a circuit that has no practical

application (and that circuit is NOT the antenna NOR its ground screen).

In short, just what do you think you are achieving (another ambiguity)?

Hi Dan,

Taking up your postings in reverse order, I can see one problem and
that is emblematic in the question above. Basically it defines a
solution in search of a question. The problem is to figure out what
question you answered by taking the measurements.

This is not an auspicious beginning.

>The antenna is a loaded vertical over a set of untuned radials. The feed is 50
>Ohm coax with a 1:1 isolation transformer at the antenna.

>I intend to run a separate coax for measurement purposes to the feed point,

This single statement introduces too much complexity for your stated
goal of taking measurements. There are rather more conventional ways
to accomplish this.

>stimulate the antenna
>with a 10 mw signal at the operating frequency, and measure the voltage across
>the antenna feed and the ground connection.

"And ground connection?" If your isolation transformer is working,
there is no need to - unless, of course, you are simply interested in
knowing this fact, or are going to put it to some particular purpose.
However, you are approaching this with no stated purpose, so this
ambiguity is simply accelerating your Drift velocity.

>Will the voltages indicate the relative RF impedance of antenna (including
>loading coil) versus the ground?

If you are treating the untuned radials in relation to ground, you
really need to describe ground. It is not so easily achived as
driving a nail into the mud and declaring that's your reference.

>If the ground were near perfect the voltage at
>the feedpoint should be close to zero.

"If" comes with magnitudes of error that can only be imagined. From
this point on, you can make your measurements and be guaranteed they
can fit any purpose - "If" you ignore the error.

>These voltages should indicate the power
>disapation difference between the antenna and the ground.

They will simply represent the potentials distributed throughout an imaginary land mine field. Tap dance with care or you may have to sign off as Stumpy.

Dan, The only way you will get a valid measurement is with your 1:1 transformer, coax, and your vector voltmeter. I guess if you are having problems with the vector voltmeter you can do the same, with less accuracy, using a dual channel scope, and directional coupler.

Maybe I should have defined what I meant when I said floating. I think
we have been talking about a DC grounded element, and that's what I
meant with respect to floating.

Virtually all of the homebrew yagis that I have seen, and most of the
commercial are gamma match, or T match. The gamma is not going to carry

the ground through, but is used almost exclusively on 6 meters where driven elements are rarely insulated from the boom. 2 through 432 are T matches and that DC grounds the driven element regardless of how it's mounted. Going up we see mostly loop yagis, and I've never seen one of those that's not grounded. I know there are regular (non-loop) yagis used 902 and up, but I never seen one to see how they are driven.

So, for me anyway, the generalization works.

And I'm just watching Silverstone, Ian, so don't tell me how it went!

I don't have a lifetime to spend picking nits with Cecil, but I do resent his immediate implications I haven't looked at the closely for a long time.

If anyone goes to places where people have multiple antennas, you'll find the overwhelming observations are that DC grounding doesn't make a bit of difference outside of one single exception. That exception is when a physically realitively large antenna that is exceptionlly well insulated is allowed to build up a charge, in which case when it breaks down a dielectric someplace the arc causes noise.

I've been through this stuff hundreds of times with antenna on tall towers and tall buildings, and found that changing from traditionl elements to closed DC path elements doesn't make a noticable difference except in the case where the element is large enough and has low enough leakage that it can change to the point of breaking down a dielectric.

In my experience the vast majority of noise people complain about is caused by corona from the element or something in the immediate area of the element.

There is no point repeating the same examples 50 times, people who are curious and have the resources will see that higher antennas, even when hit by the same particles, are always worse than lower antennas and that plumber's delight Yagi antennas are every bit as haunted by P-static as dipole-element Yagi antennas (as rare as they are).

My shunt fed towers were just as useless as floating towers, and my floating arrays of verticals in largte receiving arrays with no real DC path at all are every bit as quiet as beverages which have DC paths. As a matter of fact it makes no difference at all if series caps are added at the ends of Beverages.

Now I'm sure there will be some cases where people disagree with this, but anyone who can A-B-C test antennas will find that other than a pop or arc across a dielectric from antennas that accumulate enough charge to exceed charge leakage the only thing that really matters is how "pointed" the antenna is and how exposed the points are to the air around the antenna.

All that crud hitting the antenna isn't significantly different in potential than the air around the element, it just has a lower impedance. It's a better current source, but the particles themselves hitting the antenna don't make the noise.

As a matter of fact, it is rather silly to claim the particles discharging make noise and then at the same time claim that a DC path

somehow reduces or eliminates that noise. The CLOSER the antenna would be allowed to float to the potential of the particles the LESS change in potential would occur. Pulling the element to earth would make each tiny discharge worse and make more noise, not less.

As a matter of fact that's another reason why a quad array in inclement weather has less P-static noise than a Yagi. The parasitic elements being well insulated CAN float more towards the potential of the air around the quad. The quad has a few things going for it the Yagi never has. It does not have sharp protruding ends out into space that encourage corona, and as a general rule has parasitic elements that are very well insulated from ground.

Not much makes sense when we think for a while about the alternative theory that is all about a closed DC path to earth, especially since the vast majority of Yagis have the same path yet are worse at P-static when at the same height.

Hi Frank,

Thanx for filling in one of the gaps, what I called the mystery box.
I'd forgotten Dan had been posting about his use of a vector
voltmeter.

Dan, this is one of your habitual problems of describing the problem
at hand. You are making presumptions that all your correspondence
before you has been held in suspension to consider every posting you
make ever after. Always fully describe what you are doing, and why
you are doing it.

However, the matter of making the measurement is still problematic.
Scope probes have spring-like clips used to secure them to the point
or wire they are measuring. These are properly called "hoods" and in
most cases are removed if you are going to probe a circuit board
trace. That probe end is coaxially surrounded by a ground ring, and
scope probes often came with an accessory kit that would have a
special adapter that fit on this and extended a barb like a bayonet.
This barb was an extension of that ground ring to find the ground
point for the circuit board measurement (it presumed a ground trace
was within a quarter inch or so of the measurement point).

Barring this fine touch, that same accessory kit would come with two
alligator leaded wires with snap attachments that would fit around the
probe/cable attachment to exposed ground of the coaxial cable.

Depending upon how high the frequency, or how fast the rise time of the measurement, you could use the longer, or would be forced to use the shorter lead. If you were out for accuracy, you used the barb already mentioned.

This, of course, reveals the necessity of both grounding for reference, AND making it a short path so as to not make your probe part of the circuit. It hardly matters if you use a 10:1 or 100:1 probe, because if you don't use these short leads or the barb, your 2 meter antenna has probably just doubled its length in a very unpredictable manner.

Do you think the people who report the problems that you haven't
experienced and don't understand resent your assertion that they
believe in magic? The actual magical thinking is asserting that
charged particles don't transfer part of their charge to bare
wire antennas.

> In my experience the vast majority of noise people complain about is
> caused by corona from the element or something in the immediate area of
> the element.

That may be true but we are not discussing corona noise. Exactly
where do I go wrong in the following explanation?

1. A highly charged particle encountering one element of a bare
copper wire dipole will transfer approximately half its charge
to the wire.

2. A charge unbalance between the two elements of a dipole will
cause a differential current to flow in a link coupled system.

3. The differential current may be detected by an RF receiver.

> Now I'm sure there will be some cases where people disagree with this,

> around the antenna.

This is simply a false statement. Many desert hams, like
myself in the 1990's, have experienced another kind of noise.
I've never experienced it from snow, but I can understand
how it could happen with snow falling through dry air. The
snow phenomenon has been reported here on this newsgroup.

> All that crud hitting the antenna isn't significantly different in
> potential than the air around the element, it just has a lower
> impedance.

Absolutely false! Charged dust particles are a fact of life
in the Arizona desert. There is often not enough moisture in
the air to discharge them. Your limited experience is showing.

How often does the relative humidity get down to 10% with
high winds and dust in Georgia?

> As a matter of fact, it is rather silly to claim the particles
> discharging make noise and then at the same time claim that a DC path
> somehow reduces or eliminates that noise.

I didn't claim it "reduces or eliminates that noise". I claimed
it eliminates arcing which is certainly a type of noise.

> The CLOSER the antenna would
> be allowed to float to the potential of the particles the LESS change
> in potential would occur. Pulling the element to earth would make each
> tiny discharge worse and make more noise, not less.

My problem was that 1/2 of the antenna was at DC ground potential
and the other half was floating which is typical of a store-bought
G5RV. That seems to cause the worst case of arcing. But it is simple
physics to realize that each particle acts independently. The charge
transfer from each particle causes a tiny differential current between
the two elements of the antenna. Millions of unsynchronized collisions
per second certainly would produce differential RF noise.

A link-coupled balanced dipole system would probably never arc but
there would be a differential noise pulse through the receiver as
described in the graphic in my other posting.

3846. Wide bandwidth ladder line J-pole for 6-Meters

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-11 23:36:36 UTC
From: Chuck Olson <chuckolson01@REMOVETHIScomcast.net>
Message-ID: <5ZWdnbe8ZP27NBHZnZ2dnUVZ_vudnZ2d@comcast.com>
Source record: 58038

I've been working on a ladder line J-Pole design for 6m, but have had very little luck until today. The problem has been critical tuning and narrow SWR bandwidth. The improvement came today when I implemented an idea I had concerning the severed piece of wire that "just goes along for the ride" in the ladder line after cutting the 1/4" gap for the 1/4-wave shorted stub. I figured that many successful 50 MHz J-Poles are made from copper tubing because the thicker elements give it good bandwidth. My idea was to make use of the extra wire and connect it at top and at the gap to the radiator side, making the half-wave radiator act as a much thicker element. My 2:1 bandwidth went from 300 KHz to 2 MHz.

The resulting antenna design is very straightforward, using the Velocity Factor of 0.91 for the 1/4-wave stub and 0.95 for the radiator. This essentially sets the radiator length equal to the standard 468/F dipole length. If you analyze the operation of the very successful "Open Stub J-Pole" that Arrow makes, you will find they use the 0.95 FV for both the radiator and the stub, which is appropriate in their open design. So that pointed me in that direction as far as cutting lengths are concerned. The only remaining question was the location of the feed tap for 50-ohm cable. I used alligator clips on the coax to find the best position, and that turned out to be 4 3/8" up from the shorted bottom end, with the shield going to the gap side. My rig sees a 1:1 SWR from 50.0 to 51.2 MHz, and it gets to 1.6:1 at 52.1 MHz. With this information, it should be easy to design one that takes full advantage of the antenna's bandwidth to provide operation over the widest segment of the 6M band.

My intuition told me that there should be some advantage to using 450-ohm ladder line compared to 300-ohm twinlead. Maybe this extra bandwidth is it.

73,

Chuck, W6PKP

A large scale demo of this effect can be seen during volcanic
eruptions, when large amounts of dust are thrown into the atmosphere at
high speeds. Lightning happens.

http://www.guardian.co.uk/life/feature/story/0,13026,1368962,00.html

It is not certainty, but particles rubbing against each other do a
pretty good job of building up static.

3850. Re: measurements at the antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-12 00:53:00 UTC
From: dansawyeror <dansawyeror@comcast.net>
Message-ID: <VuCdnQ4c0fXHJhHZnZ2dneKdnZydnZ2d@comcast.com>
Source record: 58042

All,

There have been replies with some good comments and recommendations for not taking meaningless measurements.

First, the objective: Modeling software predicts a loaded vertical with a 'good' ground will have a low input impedance. This is a step on the trail to measure that impedance.

Second, a vector voltmeter, when feed by directional couplers can be used to measure impedance angle and therefore resonance. It can also be use to measure the forward and re-flected power.

The setup is a calibrated signal generator, connected to a 7904 scope (A plug in) for reference purposes only, connected to a pair of couplers connected to the vector voltmeter, connected to test antenna. The frequency is 147 MHz. The system is near resonance. The voltage measurements are taken with a pair of 10x probes, connected to a dual channel plug in (B plug in).

There is no significant change to the signal or the vector voltmeter readings when the probe leads are attached. The phase changes by less the 10 degrees and none of the amplitudes change noticeably. I do not believe the measurement system is materially influencing the measurements.

The next step is to make a current probe to attach to the base of the antenna. The result is the two 'independent' systems, the couplers and the vector voltmeter, and the voltage and current probe, should yield similar antenna impedances.

- Dan

It looks like I left out the design frequency that resulted in the 2:1 SWR bandwidth from 49.54 to 51.53 MHz, and that was 51.13 MHz. It looks like there's an offset of +600 KHz between the frequency used to determine cutting length and the actual center of SWR bandwidth. But once that's known, the design can be calculated for precise frequency coverage.

Maybe we should call it a "Fat-Wire J-pole" - - feel free to offer alternatives - -

73,

Chuck, W6PKP

Only when it is AT THE FREQUENCY the receiver is tuned to.

So when you provide a DC path that does not short the antenna at radio frequencies, it does nothing.

The only exception to this is if the charge actually causes something to arc, but even then it is a long term buildup of charge.

> This is simply a false statement.

I haven't lived in Georgia all my life. Most of my experience with this is actually in Ohio, but on other reflectors like TowerTalk everyone seems to share the same common experiences.

We agree there. So why are you arguing?

If it charges the antenna to the point where a dielectric fails the sudden change will make a terrible noise and may even cause damage.

This is why no one should have a large element high in the air that
does not have a leakage path.

> > The CLOSER the antenna would

> per second certainly would produce differential RF noise.

In that case a ground on the floating side would make no difference, or
if anything make it worse. Think about it, or draw it on paper. The
charge differential (as you say above) is between the floating
particles and the earth. The greater the charge difference, the larger
the amount of charge transferred (as you said above).

If we agree on what you say above, the "millions of unsynchronized
collisions" would not impart less charge to the antenna when it is
closer to earth potential, they would impart more.

The fact is a dc path doesn't change a thing with one single exception,
the dc path prevents an antenna from building a charge in the
capaciatnce of the system, and prevents that voltage from building to
the point where some dielectric fails. Indeed that happens, and that is
why large high antennas should have a leakage path to earth.

Even on a clear calm day my 160 dipole at 300 feet, if I let the coax
dangle a few feet above earth, will knock a person for a loop when
touched. Inactive power lines, when open circuited, have to be clamped
to ground for the same reason. On a windy day the recharge rate of the
dipole is faster, and faster still in inclement weather.

When the weather is bad, there is corona off the antenna that makes a
sizzling sound that starts out as a series of slow pops and builds to
the point where it almost turns musical or tonal. If lightning flashes
even far in the distance, it immediately stops and rebuilds. The higher
the antenna and the sharper and more extended the ends, the worse the
problem is. Even when no moisture is hitting the wire.

w8ji@akorn.net wrote:
> You can a call me a liar if you like, but it doesn't change the facts.

Being ignorant doesn't make you a liar. The fact is that
many hams have experienced charged particle noise. Your
denial of such doesn't change the known facts.

The meaning of most of your posting escapes me so I will
just summarize my position.

When I lived in the Arizona, clear-sky wind-driven charged
dust particles transferred lots of energy to my bare-wire
G5RV. It caused arcing whether the outside braid was grounded
or not. It only happened when the wind was blowing and
the humidity was very low.

I'm not sure what your point of disagreement is so help
me out.

Do you agree that a charged particle will transfer energy
to the bare wire in a dipole when it touches it? If not,
why not?

If the antenna were link coupled, do you agree that the
above transferred energy will try to equalize between the
two dipole elements? If not, why not?

Do you agree that the equalizing of the charges between
elements would cause a current to flow through the link?
If not, why not?

> Most vhf manuals detail this effect! Jim NN7K

Dunno...I don't see much difference as far as the polarity
of the antenna. It's more the polarity of the noise source,
and it's radiator. I've got both horizontal and vertical yagi's
on 2m, and I've seen many times when the local line noise
was much worse when horizontal. But I blame that on the
noise being radiated mainly by horizontal power lines.
I see cases of noise with both polarities, or mostly
vertical, or mostly horizontal. Just depends on the source
antenna. You usually see appx 20db attenuation when
cross polarized.
As far as Ken's loop vs inv vee, if the vee is picking up more
noise, that just means the vee is the best antenna at picking
up that particular noise and at that direction and angle.
If he were to transmit on the two antennas, and receive
them from the noise source, using the sources antenna,
the vee would be received the strongest more than likely.
It's all reciprical. Noise is rf just like any other signal, and
obeys the same rules. If a certain antenna picks up more
rf of any type, noise, or desired, it's the best antenna of the
bunch to receive that source of rf. Thats one reason why I
often chuckle about "noise problems".. As long as it's not
local or common mode pickup from the shack, that just means
the antenna is working, and doing what it's supposed to do.

No No No White noise is used where you want an equal distribution of
amplitude across the spectrum you are measuring.

Pink noise is used where you need a response that is similar to the
graph of human hearing for example. It is nonlinear across the bandwidth.

1. Too bad you have to work for/with people like that. " ... last year's work" is correct. The possessive does not exclusively denote ownership. It also denotes the "of or pertaining to" relationship, as in "Cleveland's bus system."

2. I just went to the McGraw-Hill Learning Center

http://highered.mcgraw-hill.com/sites/076743000x/student_view0/chapter1/apostrophes.html

and took their apostrophe quiz

Results Reporter
Out of 17 questions, you answered 17 correctly, for a final grade of 100%.

17 correct (100%)
0 incorrect (0%)
0 unanswered (0%)

Here's the most interesting one:

Last years womens softball team is much better than this years. [The stem omits apostrophes.]

C) Last year's women's softball team is much better than this year's.
Feedback: Correct!

3. Despite the absolute correctness of the apostrophe for the plural of numbers and letters, I see a lot of acronyms and abbreviations made plural by the addition of an "s" without the apostrophe and I don't flinch. I think the language is evolving regarding acronyms, which, after all, are less than 100 years old. Therefore, I vote to accept "SWRs."

I have a similar inability to relate, but it has to do with math. Most of it I ever studied came easily to me. However, some poor souls cannot regard simple real life situations in terms of math. For example, E-max for my lovely bride is the checkbook. That's it. [How many square yards in a 9 x 12 foot carpet? Duh - what color is it?]

I learn new tricks every day. Morse Code isn't one of them.

Hi Dan,

The use of 10x scope probes is an illusion at best, and certainly not
the way the "pros" do it by a long stretch.

>There is no significant change to the signal or the vector voltmeter readings
>when the probe leads are attached.

Compared to what? This is again an example of ambiguity that offers
nothing tangible except a "feel-good" kind of experience. Do you know
why there is "no significant change?" If you replace a 1x feed with a
10x probe, wouldn't you expect change? Your faith is based on what
would normally set off red lights and have warning flags being waved.

>The phase changes by less the 10 degrees and
>none of the amplitudes change noticeably. I do not believe the measurement
>system is materially influencing the measurements.

This is a faith-based feeling instead of rational expectation. It is
overwhelmingly obvious by your statement above that the system is
wholly out of whack with expectations.

A simple review of the actual probe can be instructive in this case to
explain why you see little change, and why you wouldn't use a scope
probe in the first place. Most 10x scope probes are not rated into
the VHF. The 10x probe is generally a 10 MOhm resistor with a
parallel 10pf variable capacitor. Simple math would reveal that at
147 MHz that cap presents about 100 Ohms reactance - hardly worth the
effort and certainly no where near a 10x function. The equipment 10x
probe (not a 10x scope probe) has only 2pF of capacitance (5 times the
reactance of a scope probe) and a tenth of the 10x scope probe
resistance. What you are reading as scaled voltage is not what is
present to be measured, but a complex, phase shifted value.

You have absolutely no rational basis to use a 10x probe of any kind.
Skip this unnecessary elaboration.

Hi Mike,

This hypothesis was a home-grown and hand rolled fantasy.

> I don't doubt that the problem has been solved (if it exists in the
>first place).

Oh, there is a problem alright: Making the lesson penetrate a quarter
inch of skull with more success than RF struggling through an
imaginary 4 foot skin depth of water problem.

3865. Re: measurements at the antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-12 09:19:45 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <128qcdkbphel65f@corp.supernews.com>
Source record: 58057

In addition to the weaknesses of scope probes mentioned by Richard is the ground lead. Even a short one has considerable reactance at VHF, and its use will promote common mode current on the outside of the probe cable. Any decent scope measurement at very high frequencies is done with an adapter which connects directly to the ground ring near the end of the probe, through a very short conductor. An example is the one sold by Tektronix, P/N 013-0085-00 the last time I checked. Even it must be used with some care.

I don't see any hope in your making meaningful measurement with the setup you describe -- there are too many potential sources of serious error.

Roy Lewallen, W7EL

why do dislike 5/8 wave antennas? can you point me to any references. i realize there is a high lobe.

i have an old Low Band Dxing, and ON4UN seems to like 5/8 on 40. i personally tried a 5/8 vertical on 10 with bad results. however, my ground system was terrible.

i plan to try 5/8 with full 120 * 1/2 wave radials.

i remember at one multi-single, we had a 1/4 wave 10 meter at 100 feet that was even with the beams sometimes.

i believe K3LR mentioned he was building a 10 meter 5/8 wave 4 square. was he kidding?

one thing i've been pondering is a vertical colinear. 1/2 wave over 1/2 wave. i have not modeled it.

is there any free modeling software?

i noticed that you stated that phased arrays with elements separated by more than 2 waves don't work well. i was thinking of a vertical array, either inline or broadside.

just some random thoughts:

a ground system for 10 meter 4-square would be 240 waves worth of wire (minus some because of shared radials). that's 8000 feet, at 5 cents a foot, $200. you can set up a beam at 30 feet for that price.

scaling up to 40 meters, that's a lot of wire.

Hi, Jeff,

Thanks for the reference to a similar design. The Slim-Jim may perform as well as the thing that I put together, but my implementation added a connection from the bottom end of the radiator opposite the gap to the wire end above the gap. Computer simulation may reveal that both perform identically despite the difference. In that case, I would suggest leaving out that bottom connection since it's a little extra work. The Slim-Jim never came up in my search effort to find a good J-Pole design, so I'm glad to see this promising area of further search.

The real issue is probably that HF privileges are probably just not that important to you. I have enough hearing problems that learning Morse was darn hard. 60-70 db tinnitus, (est) and hearing holes in the higher frequencies, and just can't hear for crap.

When I got my Tech license, a lot of people told me that "Morse code is going away any day now, no need to learn that stuff".

I'm glad I didn't listen to them - I have had HF access for 6 years now, and if learning Morse was the price I had to pay, then it was worth it. YMMV

Since it may be a couple years more until the Morse code test is eliminated (if even then) my decision is looking better all the time.

I'm modeling the thing in 4nec2 now. I get different results than both of you, so I need to go back to the drawing board.....

I've always wondered though if some mfgr's fudge a little on their lengths to cloud the issue a bit. But then I make my antennas, so I never bought one to check.

You can use the free demo copy of EZNEC by driving the
collinear with two sources and varying the phase angle
between them. Then you can design an appropriate phasing
network. I don't think the lumped inductive reactance
available in EZNEC will yield an accurate phase shift
and the free demo will not handle enough segments to
model a helical coil.

How about IDEA pronounced "IDEer"

3886. 2 Meter QUAD - Balun / SWR question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-12 19:17:44 UTC
From: "K. Hastings" <myfamilydotcom@hotmail.com>
Message-ID: <s5jjg.21651$A26.486919@ursa-nb00s0.nbnet.nb.ca>
Source record: 57978

I recently built a decent 3-element 2 M Quad that fits inside my insulated attic (just barely) and is all connected to my shack. Worked great... The problem now is that the SWR is very high (>>3:1) on all freqs above the 145 MHz channels.

I think that the Quad, when tested inside the house had a great match across the band from what I recall.

This thing is fed with RG-8 and I purposely put a whole bunch of turns into a 5" coil near the feed point, and I'm wondering if I should have done that at all now. I'm sure that the match would be different regardless since it's now located in a different space, and I understand how that can change things.

It's dark and itchy up there - before I go up there and unwind the whole BALUN, can you guys tell me whether or not I even need that thing, or have I got another problem.

FWIW it works great - decent gain and nicely directional - but the SWR is too high, and it resets all the programmable thermostats clocks in the house when I key up (interesting RFI huh?) which my attic ground-plane DOES NOT do.

help?

Hi Kevin,

You have just defined its environment.

>This thing is fed with RG-8 and I purposely put a whole bunch of turns into
>a 5" coil near the feed point, and ... it resets all the programmable thermostats clocks in the house
>when I key up (interesting RFI huh?)

Do you find the hidden clue when all the excess verbiage is cleared
away?

A whole bunch of turns is not very specific except to indicate you
probably overdid it and negated any benefit you might have expected.
Would it help to say fewer turns on a smaller form?

That, however, is probably not what is responsible for the SWR. You
are going to have to tune the antenna in place AFTER you successfully
isolate the drive line.

Hi Richard

As you know, I have been getting good results with the high permeability ferrite tubes for decoupling the coax feed line on my balanced antenna. I bought a bunch of inexpensive ferrites that were intended for absorbing RFI, from All Electronics. Would it be practical for Kevin, the orginal poster, to get decent results with a few ferrites covering the coax where it seperates from the boom??

Jerry

Hi Jerry,

Sure, but you have the advantage of being able to measure the Z of
those ferrites. However, buying them rummage style and hoping they
will work does not always bring a satisfactory solution.

Youze guyz are arguing about two cases of "arcing" and going off on
tangents.

First case is as Cecil has experienced and 'splained, is the static
electricity charge buildup and corresponding noise/discharge on conducting
"things" due to charged particles - aka rubbing the glass rod with furry
animal coat. The part (antenna) gets charge from the "rubbing" by the
particles, air, whatever...., builds up voltage and is looking for discharge
across anything that provides jumping points for the voltage accumulated.
This is the case of clear Arizona skies, with no clouds in sight, just wind
doing it's "thing". W8JI might not believe it, but it IS the fact.

Second case is, as it was hotly discussed on Contest and other reflectors,
and first mentioned by VE3BMV, W0UN, W4ZV and others, in conjunction with
lightning and protection against it - is the static electricity charge
buildup due to the clouds "rubbing" in the air and creating huge static
charge between the clouds and the earth ground and objects "residing" on
ground and connected to it. There the highest , mostly grounded, objects get
"first crack" at the "touching" the voltage gradient generated by the static
electricity buildup. If there is a sharp object, it will start "acting" by
generating corona and "peacefully" discharging the potential. If it can't
keep up with rate of "peaceful" charge, it will invite lightning strike. The
corona can be visible at the times, or it doesn't have to be.

Then we get cases when the high antenna is the highest object and will be the "discharger" and the noisiest one. That appears to discharge the charge from the area (space) in the vicinity of the high (object) antenna - umbrella. You can look at it as a capacitor plate, collecting charge from the space around it. Lower antennas get benefit of discharged space and are quiet. This is especially noticeable with stacked antennas. The top one would be typically 20/9 noise - hash, the lower one would be dead quiet. The same then applies when you have higher object than antenna in question, that antenna could be quiet, but when (beam) is aimed at the higher object (the static discharger) it can receive noise, but at much lower strength.

This umbrella effect seems also work as a lightning prevention by discharging the space in the vicinity of the structure and preventing critical buildup of voltage causing creating of leader and inviting lightning strike (99.9%). I and others have noticed practical elimination of lightning strikes to our installation when sporting tall, grounded towers with large antennas (capacitor plates). They seem to bleed the deadly potential from the air "sandwich" between the sky (clouds) and ground and objects under the "umbrella" and making lightning look at pointy grounded objects before and after our "ugly" antennas and discharge their deadly megawatts there.
So large antennas on tall towers - GOOD to repell lightning. Pointy, sharp objects - BAAAAD, they attract lightning. So, one can protect his QTH and radio junk by either inviting lightning to strike the lightning arresters and hopefully conduct them to ground, or better, repelling it by the Antenna Umbrella - the biggest mother antenna (capacitor plate) on the tallest possible and well grounded tower (no protruding VHF vertical pointy junk above) you can put up.

Scientwists might not find this believable, but those with big towers and large grounded antennas noticed remarkable absence of direct lightning strikes vs. when previously sporting pointy verticals or towers without antennas on the top.
When I had my TH6 at 60 ft. and above it, way up 2m Ringo Ranger on a mast, I got visited by direct lightning trice within 2 years. When put up Big Bertha with 60 ft boom Razors, never again over 10 years. Not very statistically scientific, but very noticeable. Same experienced by W0UN, W0ZV and others.

Soooo, the judge's verdict is: Cecil is right, W8JI is partially right, jury to judge by the above 'splanation of this humble servant. :-)

I hope this clears some static static.

It really doesn't matter if the vessel has a draft of 4 feet or 24
feet,as the coupling to the seawater is to the hull/water boundry
which is the same as the surface of the water from the RF point of
view. Skin Effect, or Skin Depth @ any frequency is a Surface Effect
and that surface is the hull/water boundry, for any hull material.

> why do dislike 5/8 wave antennas? can you point me to any references. i
> realize there is a high lobe.
>

Anyone who understands how a 5/8th wave works, and who isn't captivated
by the popular fantasy that the length makes the gain, would know what
the problems are.

A 5/8th wave antenna gets its gain from the ground reflection. The
ground reflection is what form the "image" that produces the gain.

Unless the ground is very large and flat and highly conductive, the
5/8th wave antenna concentrates most of its energy at high
angles.....not along the ground.

Move the 5/8th wave up above the ground or use a poor ground, and
maximum low angle FS comes from shorter antennas.

If you look at:

http://www.cebik.com/gp/58-1.html

you will see a 5/8th wave on 80 meters with a large flat ground system
not only gives marginal gain over a 1/4 w, it also has a null aat the
most useful wave angles for most work.

If you elevate the 5/8th wave or take away the good ground system, the
very small advantage it has goes away.

As a matter of fact AM BC stations, despite their large ground systems,
abandoned the 5/8th wave many years ago. They found in the real world
use of 5/8th waves instead of extending coverage they reduced coverage.

3902. tri-band HF beam for portable ops ?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-12 23:09:05 UTC
From: Thierry
Message-ID: <448df40f$1@news.vo.lu>
Source record: 57994

Hi,

I am interested in buying a triband yagi (20-15-10) for portable operations
But I suspect such antennas, most being made of aluminium, to be heay (over
10 kg) and maybe not easy to dismantle regularly
I review on my webiste various portable configurations, so I know quite well
the problem.

I would like to know if some of you have testes successfully such
installations using the minimum of hardware (transportation using an
ordinary car, not a break, not a pickup and not a 4x4, installation by only
one person, small beam placed on a single pod 8-10m high, one guy-wire, no
rotator) for a on-day activity, the Tx working on battery.

If you work in the field with a small beam, what difficilty do you
experimented (weght, wingspan, other)?

Thanks

Thierry

Hi Richard

I realize that I place way more emphasis on "Amateur" in the HAM concept.
I'm not inclined to depend on using only the best component. But, it seems
that any of those ferrite tubes that were intended to be used to minimize
RFI will work well at 144 MHz. So, since they are cheap and available, I
thought it might be worth trying some inexpensive, high permeability tubes
instead of coiling the coax into a coil.
I did measure the impedance across a loop of RG 223 with 4 tubes around
the outside. The problem I come up with is my ignorance of *whats needed*
for adequate decoupling of the balanced antenna from the outside of the
coax.
I depend on you to shed light on alot of the things I try.

Jerry

perfect example. a large scale dry example of colliding dust particles
building an electric field, without need for them hitting a metalic
conductor. dust particles pick up charge by bouncing off each other and the
ground, there can actually be quite a high electric field built up.

3905. Re: Wide bandwidth ladder line J-pole for 6-Meters

Newsgroup: rec.radio.amateur.antenna

From: Chuck Olson <chuckolson01@REMOVETHIScomcast.net>
Message-ID: <Ts-dndx_b-BRkBPZnZ2dnUVZ_oydnZ2d@comcast.com>
Source record: 57997

Today I clipped out the connection I had made at the bottom of the radiator, and the SWR bandwidth remained 2MHz as is was with the connection. The group of SWR measurements moved up an average of 150 KHz from my readings with the connection, but otherwise the performance of the "Slim Jim" configuration is identical. The length of the gap may now serve as a tuning mechanism, which wasn't a feature with the bottom connection, and the archives show some builders made good use of that facility. Thanks for spotting the similarity, Jeff. My 6M antenna will no doubt be better for it.

W8JI,

thanks for your comments. i must have missed that cebik article, so i will read it.

now i reread the antenna section of ON4UN's book, and he does say 5/8 wave are best for very poor or very good (saltwater) ground. so i am probably wasting my time with 5/8 waves, although i will try it for the hell of it.

i bet ON4UN used a 5/8 on 40 because he needed the length for 160 and 80 in the multiband vertical.

hmm.

this is a good idea. cebik site has some articles about EDZ beams and
colinears and arrays.

i should probably go with a 4 element 10 meter Yagi, but i want to
experiment with some alternatives.

Hi Jerry,

Just think of the antenna as the "source" and consider its
characteristic Z. Now consider the common mode circuit of the
transmission line and its Z. So often this is an unknown, and if we
were always lucky, it would be a half wave multiple to present a very
high Z indeed. Thus 'twould be the end of the story.

How high is high enough? I offer three values for choking:
3 times antenna Z at a minimum;
5 times is practical;
10 times is lab grade.

So, tell us what those 4 tubes measured?

But that effect is common no matter where we live. As I've said several times, a high dipole here for 160m charges enough to knock you on your rear on a calm sunny day if the coacial line is well insulated from ground.

It is not wise tol have a large high antenna that was well-insulated from ground, since the accumulated charge can suddenly discharge through a series capacitor and damage equipment.

Utility companies must ground unused wires that run for miles to prevent build up of charge, so that is not something that just occurs in arid climates.

> Do you agree that a charged particle will transfer energy
> to the bare wire in a dipole when it touches it? If not,
> why not?

Of course it will IF it is at a different potential than the wire.

> If the antenna were link coupled, do you agree that the
> above transferred energy will try to equalize between the
> two dipole elements? If not, why not?

Of course it will.

> Do you agree that the equalizing of the charges between
> elements would cause a current to flow through the link?
> If not, why not?

Of course it will.

I disagree wth your contention that the link, if the noise comes from each particle hitting the antenna, will reduce noise. That's the part that makes no sense.

Maybe you can explain why the link (or folded element) would reduce that noise.

3919. HF antenna for yacht / boat

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-13 09:13:29 UTC
From: John Laczik <John@laczik.org>
Message-ID: <e6lvjpahc1@news.ox.ac.uk>
Source record: 58011

Any recommendations for a *simple* antenna that can be used
on a yacht/boat to receive ~500 kHz, and to receive/transmit
in the HF amateur and marine bands (1.5 MHz ~ 30 MHz)?

Currently I am thinking about a length of wire between the
stern and the top of the mast, fed via an ATU at the stern
end. I can make the wire ~50' long. What is the optimum
wire length? As long as possible?

Thanks,

John

Hello John,

The best starting point is probably the
installation guides available at
www.icomamerica.com and www.sgcworld.com.

Those two companies sell ssb radios and automatic
antenna tuners. If your tuner is of a different
make, you might search out information on it.

From there, you can simply do google searches on
any aspects not covered in those manuals.

The ARRL has published a book on marine
installations but I have not seen a copy yet.

Good luck.

Chuck

"Characteristic impedance" is not the impedance associated
with choking requirements. That probably should be
"feedpoint Z" (source Z for receive).

For standing wave antennas the characteristic impedance
and the feedpoint impedance are usually quite different.
For a #14 wire horizontal 1/2 WL dipole at 30 ft., the
characteristic impedance is in the ballpark of 1200 ohms
while the feedpoint impedance is in the ballpark of 60
ohms.

I have a low, 30 feet or so, 80 meter dipole fed with ladderline,
through an mfj 989c tuner. Hot humid clime (Texas). Is the ground wire
on the back of the tuner, going to a ground rod, enough to bleed off
electrical build up?

Almost anything is enough to do that. The charge rate is extremely low.

My 318 foot tall insulated tower had a measured charge rate in the
ten's of milliamperes as measured during approaching thunderstorms.

Of course taking care of a lightning bolt or EMP from a lightning
strike someplace around the area is another story.

Source record: 58016

I did much the same thing but used a dipole "V" configuration with the apex
at the tip of the bow and each leg going to opposite sides of the flybridge.
Overall length was 32 feet.
I used an SGC-30 tuner and was able to load on all bands from 160-10. I
used the stainless steel railing all around the boat as the ground and it
seemed to work well. Lots of DX on 20M, including England with 5 watts
using a Yaesu FT-817.

This arrangement worked but the legs of the dipole going down to the bow
caused deckhands to get tangled feet when we were docking etc; so I scrapped
this system the next year in favor of the Shakespeare 23-ft marine whip with
the SGC tuner. Worked much better.

Good luck

****

I have only noticed the charged particle arcing in Arizona when
the wind was blowing and that is what I am reporting.

> It is not wise to have a large high antenna that was well-insulated
> from ground, since the accumulated charge can suddenly discharge
> through a series capacitor and damage equipment.

Where does the accumulated charge come from if not from charged
particles? If the antenna is link coupled, the charge equalizes
between the two dipole elements and, in my experience, doesn't
arc.

>> Do you agree that a charged particle will transfer energy
>> to the bare wire in a dipole when it touches it? If not,
>> why not?
>
> Of course it will IF it is at a different potential than the wire.
>

>
>> Do you agree that the equalizing of the charges between
>> elements would cause a current to flow through the link?
>> If not, why not?
>
> Of course it will.

Seems we are in agreement that charged particle RF noise can
therefore be picked up by a receiver as Reg says above. It is
only logical that it will be worse when the wind blows causing
more charged particles to encounter the antenna wire. And,
as shown below, it is only logical that a folded dipole would
transfer less of that noise to the link than a non-folded dipole.

> I disagree with your contention that the link, if the noise comes from
> each particle hitting the antenna, will reduce noise. That's the part
> that makes no sense.

In my experience, it eliminated the arcing. Thus it eliminated
the *AURAL* arcing noise that my ears were hearing. Why does that
make no sense? I was very clear that my receiver was off and
disconnected at the time and that I made no RF noise measurements.
A short, or 4:1 voltage balun, or choke, or link across the
connector eliminated the *AURAL* arcing noise.

> Maybe you can explain why the link (or folded element) would reduce
> that noise.

Seems you confused my statements about aural noise with RF
noise. I have previously said I didn't measure the RF noise.

In any case, please see the pictures below to understand why
a folded element redirects the charge equalization process
away from the link.

The process of equalizing the charge on the non-folded dipole
elements causes RF noise across the link which is picked up by
the S-meter on the receiver. I observed that many times in AZ
and wish I had made some measurements. The S-meter reports a
higher level of charged particle noise during high wind
conditions and dry-air snowstorms.

Please explain what it is about the following that you don't understand.

1. The equalizing of the element charges on a link coupled dipole will cause a current to flow through the link resulting in higher RF noise readings on the S-meter during high wind conditions when more charged particles are encountering the antenna wire.

2. Turning the dipole into a folded dipole (or loop) gives a preferred localized path for the equalization of the charge. Not nearly as much RF noise current flows through the remote link.

Maybe a picture would help. Here's a non-folded dipole with a charge hitting it. In order to equalize charge with the other element, part of the charge must flow down the transmission line, through the link, and back up the transmission line to the other dipole element. Virtually all of the pulsed charge equalization process goes through the link.

```
---------CH----+ +---------------
| |
/ /
| |
link
```

****

```
+--------------------------------+
+--------CH----+ +---------------+
| |
/ /
| |
link
```

Here's a folded dipole with a charge hitting it in the same relative place. What is the most efficient preferred path for equalizing the charge with the other element? Not down the transmission line and through the link but simply straight through the antenna wire. Hint: Charge would rather take the 50 foot path of least resistance than a 200 foot path of most resistance.

Eureka! The folded dipole is less noisy during high wind conditions than is the non-folded dipole because most of the charge equalization takes place locally through the antenna wire and not remotely through the link.

BTW, thanks for forcing me to think this through in detail.

If there is a DC path to ground from *BOTH* sides of the
dipole, the answer is yes. But, looking at the 989c
schematic, I don't see a DC path to ground from one of
the balanced line outputs.

I forgot to say that your high humidity probably provides
a path to ground from the other tuner terminal. It was
only during super low humidity conditions in the Arizona
desert that I experienced the arcing process during
high winds.

Hi Richard

I have been thinking of the "string of ferrites" as a method of presenting
a high impedance to Conducted currents along the outside of the coax from
the antenna down to the radio. It is clear that a "high impedance" may
actually couple well to the outside of the coax if the length of coax is
some special length that presents a high impedance up to where the choke is
located,
I think I could have saved time if I'd asked you more questions when I was
doing the work of learning about baluns.

I didnt keep any of the data I recorded with any of the coils and
ferrites. It is easy to measure the Z of any high impedance circuit so I
could easily measure choke impedance at 2 meters.

Jerry

In the text above I was responding to the charging and arcing from a
floating antenna, NOT to the mechanism Reg was talking about below. I
have NO problem with the wire charging and arcing. But I've NEVER seen
a situation where particles directly hitting the antenna make noise,
which is what Reg was talking about below....

Why do you think it is the particle that make noise or even that they are necessary?

Allowing what you say is true, then you are arguing against yourself. As I understand it:

1.) You say the particles make the noise as each individual particle hits the antenna.

2.) You say grounding the antenna eliminates that noise.

There is an obvious conflict in those two ideas. Grounding the element for DC will not reduce the rate the rate of energy transfer to the antenna from particle, it can only INCREASE it by preventing long-term charging of the antenna closer to the potential of the particles.

I can't recall seeing any gap-sparking here in the San Antonio area.
When it's hot, it's usually pretty humid, too.

> coverage they reduced coverage.

The h-plane inverse field of a 5/8-wave AM BC vertical working against 120 buried radials each at least 1/4-wave long is calculated in theory and measured in practice as having the greatest possible field per unit of radiated power of any non-sectionalized radiator height, no matter what the earth conductivity at the antenna site.

But the 5/8 wave BC vertical does have a discrete, high angle sidelobe that, at night, can interfere with its own groundwave over an annular zone starting a few hundred miles from the antenna. Very distant coverage is provided by low-angle skywave (less than about 30 degrees), and is not affected because the groundwave is gone at those distance ranges.

But this is the reason that 24-hr, 50 kW AM BC stations use a radiator typically around 195 degrees. Its h-plane inverse field (the groundwave) is not quite as great as from a 5/8-wave, but it doesn't develop that high-angle lobe. It is popularly called an "antifade" radiator.

Yes, and you have agreed with all the steps leading up to that
noise pulse flowing through the link. It is just simple physics.
I notice you are not responding to any of the technical content
of my posting are are continuing to deliberately obfuscate
something I said earlier about aural arcing noise.

> 2.) You say grounding the antenna eliminates that noise.

Grounding the antenna eliminated the ***AURAL*** arcing noise
that was keeping me awake at night and scorching my rug when
the transceiver was powered down and disconnected from the
antenna. How many times do I have to explain that to you?

But I have no doubt that if the transceiver had been turned
on, the arcing across the transceiver connector would have
caused RF noise if not failure. And I also have no doubt that
grounding both transmission line conductors would have
eliminated the arcing and thus reduced the RF noise heard
by the receiver.

Your style of argument is making you look stupid.

> There is an obvious conflict in those two ideas.

Only in your mind, Tom. Please cease and desist with the
obfuscation and try to follow your own advice from another
newsgroup where you said nobody knows everything (presumably
including you) and everyone is capable of learning something
new (presumably including you). It's past time for you to
learn about dry-air wind-driven charged-particle noise.

Quantum Electrodynamics will tell you that even corona noise
is caused by charged particles.

>"differential" mode or "common" mode?

Hi Owen,

The Common mode. The remainder of this discussion will undoubted be known to you, so it is largely meant for our otherwise silent original poster, Kevin. The ferrites will be more or less transparent to the differential mode when the ferrites wrap around both conductors for twin lead, or around the coaxial cable.

As this discussion has been largely coaxial based, the outer conductive surface of the coax is the primary imbalance to a dipole through its "third wire" connection at the dipole feed point. It appears as one of three wires to the abstract source established at that feed point and it presents an ad-hoc Z load. The value of this load is rarely determined, except when one deliberately attempts to make their feed line 1/2 wave long (or some multiple). Of course, that means 1/2 wave for the velocity factor of the outside conductive path of the coax. This is often accomplished through cut and try rather than modeling or measuring currents, but these too would be good first pass approximations.

However, it is simpler to add ferrites as their Z is well known and rarely subject to externalities. They also allow for multiband operation. They are simple to apply. If you aren't using hi power, they are "set and forget."

In closing, it bears mentioning that this treatment should be repeated a quarterwave down the coax and away from the drive point. This, in effect, enforces a one band solution by its description, so choose the band that counts the most. I would expect it would improve other bands to some degree. I've simply distributed the same number of ferrites over a 20 foot length of coax as the second treatment instead of repeating the same lumped isolation. I cannot vouch for this method's effectivity in maintaining a null pattern in the lobes of the dipole as I never confirmed that.

>"differential" mode or "common" mode?

Hi Owen,

It occurred to me that there are two Zs mentioned and you did not really differentiate as I had.

The antenna Z will be something we all have expectations of attaining, and we quite often measure it. For the dipole we merely assign a value of 70 Ohms for this discussion.

Now, we have the Z of the "third wire" which is almost never measured, especially for every application. If it presented an equal 70 Ohms, it would then hog half the power - however, this is unlikely in the scheme of things. Let us just say it will exhibit some value that may tend to absorb and radiate power. This capacity both upsets antenna patterns and contributes to RFI and feed line radiation.

If the source is 70 Ohms and we add 200 to 700 Ohms of resistivity in line (through the application of ferrites as common mode series resistances), then we have diminished its capacity to hog power. As 1000 Ohms of ferrite resistance is easily applied, this has generally satisfied many conditions.

> Why didn't you respond to the pictures I drew for you?

Because you have unlimited time to go off into hunderds of a tangents.
I still work 50-60 hours a week.

> > 1.) You say the particles make the noise as each individual particle
> > hits the antenna.
>
> Yes, and you have agreed with all the steps leading up to that
> noise pulse flowing through the link. It is just simple physics.
> I notice you are not responding to any of the technical content
> of my posting are are continuing to deliberately obfuscate
> something I said earlier about aural arcing noise.

I must have missed it. With any AURAL noise there is alos a spark, and
that spark is accompanied by electrical noise or component damage.

My understanding was you said the HF noise in the receiver was caused
by the random particles actually striking the antenna. If so, grounding
makes no difference.

> > 2.) You say grounding the antenna eliminates that noise.
>
> Grounding the antenna eliminated the ***AURAL*** arcing noise
> that was keeping me awake at night and scorching my rug when
> the transceiver was powered down and disconnected from the
> antenna. How many times do I have to explain that to you?

Along with any aural noise is an arc, along with any arc is electrical
noise. None of that matters however. As I understand it you said the HF
noise was from particles hitting the antenna. If so, grounding the
antenna could only increase the voltage delta between the particles and
the antenna.

If you disagree, explain why.

> But I have no doubt that if the transceiver had been turned
> on, the arcing across the transceiver connector would have
> caused RF noise if not failure. And I also have no doubt that
> grounding both transmission line conductors would have
> eliminated the arcing and thus reduced the RF noise heard
> by the receiver.

If the noise was a slow popping noise caused by a series component
breaking down, I agree. If the noise was what is commonly reffered to
as P-static, the sizzling hissing or whining noise with almost a
musical note, I disagree.

> Your style of argument is making you look stupid.

Calling people stupid makes you look like you cannot have a mature discussion. Why not act mature?

:-) Sure you did even after I said it half a dozen times. :-)
You have talked about my transmission line laying on the
rug scorching it so you could not possibly have "missed it".

> With any AURAL noise there is always a spark, and
> that spark is accompanied by electrical noise or component damage.

Yes, I have said *many* times that my transceiver's power was
off and it was unplugged from the transmission line. You know
the transmission line was laying on my rug because you have
talked about that before.

> My understanding was you said the HF noise in the receiver was caused
> by the random particles actually striking the antenna. If so, grounding
> makes no difference.

I agree and never said otherwise. However, since you
insist, below I indicate how grounding would have made
a difference had I responded in a different way.

> If you disagree, explain why.

Let's say that I was stupid enough not to disconnect my
transceiver when I heard the arcing at the coax input and
instead turned the transceiver on. Let's say it didn't
suffer failure.

Would you agree that I would hear RF noise in the transceiver
every time the coax connector arced?

Would you agree that if I shorted the center conductor to
ground that since the outer conductor was already grounded,
the RF noise in the transceiver would decrease?

> Why not act mature?

It was you who once again regressed to your terrible-twos
infantile omniscient stage and just couldn't resist
misquoting me. Please don't do that again.

Perhaps I'm not pedantic enough to enjoy the courtesy of your reply. If your rug is scorched...how much current is there?

My simple question was: Is this a novel way to create a trickle charger? (When TCVR is d/c'd, of course)

Anyone care to respond?

Otherwise, I'll just lurk and observe the "drama" between you two.

Chuck,
I searched on Slim-Jim. Let me see if I understand correctly.
Slim-Jim is a twin-lead or ladder-line type J antenna with the *top* of the
half-wave 9dual conductor) radiator ends connected.
Yours has the bottom of the 1/2 wave ends connected.
Am I to understand that the Slim-Jim configuration and yours have very
similar SWR BW?
This is good to know.

Then I'd like clarification on your comment:
"... If you analyze the operation of the very successful "Open Stub
> J-Pole" that Arrow makes, you will find they use the 0.95 FV for both the
> radiator and the stub,..."

Can you be more specific about this. What is the electrical length of the
stub for said analysis? I like that design, though there is controversy
about it.

> > Thanks,
> > Dan

Dan,
I'm echoing the others on this. Using scope probes for this kind of measurenet is a very touchy undertaking at the very best, even with the best quality equipment and much experience. Other methods of measuting RF are required and used by those who know. That's why they were developed. If you do this at 10M or below, then you have more chance of getting correct results.
That being said, it is not clear what you are trying to measure since you say you are, in essence, measuring "ground". It is not clear just what you are doing. Unfortunately, from your description, the way you describe this, I feel you do not have enough technical background to understand the technical concepts well enough. You appear to have some knowledge, but not enough, in what appear to be basics, to do this.
The way you describe your technique, you are not connecting the probe ground to anything. This makes no sense. RF measurements may seem like "black magic" but it takes nothing more than *really* understanding all the basics and all the stray effects really, really well.

At least you seem to understand that "ground" is not the absolute zero reference that others seem to believe it is / can be / needs to be.

A few comments in general:
You *MUST* connect *BOTH* parts of the probe tip if you hope to get anything close to true results.
Both these connections must have no effect on the measurement.
The probe must be capable of measuring what you are attempting.
There are high frequency 10x probes, but all the other sonsiderations are even more important because they will be even more susceptable to the side effects just because they *are* capable of making the measurements.
The Shield / ground part of the scope probe and cable leading back to the scope is something which can have a significant effect on what you see on the scope face. The antenna can be inducing current into this and giving false readings. This is a major problem in measuting any high frequency signals. There must be no possibility of the scope cable picking up any signal. I have seen very misleading results when this technique is tried on digital circuits which have fast rise times and therefore high frequency components.

Good luck & 73, Steve, K9DCI

Hey, no prob.

I don't use Morse code, probably never will, unless I get into keyboard Morse.

But I did want the HF access, so I learned Morse code. It was that important to me.

As for what is right, do you know that there are thousands, maybe millions of people who can't pass the writtens? How is it right that we have any testing at all when we discriminate against them?

It isn't an insult to anyone to say that HF access isn't important enough to them that they will take the time and effort to learn Morse code. Ham radio doesn't have to be important to anyone - it's a hobby.

OK here's my take, since all the other answer'ers answered without having enough info in the first place, in my opinion...

Pink niose explanatino #12.
What you call the "pink noise" that you see / hear in an FM receiver could be that which is designed into the receiver and therefore not normally removable. You could add preemphasis to "whiten" it up. The reason is that the receiver has "de-emphasis" built in to compensate for the pre-emphasis designed into the transmitters that it will receive, which, in turn, was put there to help enhance the low noise characteristics of the FM mode of transmission. This "de-empnasis" is nothing more than a filter which reduces the high frequency audio copmponents more than the low frewquencies, thus giving it the "pink" or low frequency enhanced characteristic. The term Pink coming from the color red which is the color of lower frequency visible light and we have simply retained that analogy when referring to noise. Narrow band receivers use a simple -6 dB per octave deemphasis across the whole audio band and wide band, broadcast receivers use something similar, but it doesn't extend across the whole audio band.

So can you be more speciffic?

When do you hear this noise?
Why do you want to get rid of it?
What are you listening to?

>White noise is constant energy/Hz, pink is constant energy/octave.
>tom K0TAR

You're both right. The "classical" definition is Tom's. "White" is a
constant energy density. "Pink" is 1/f, which gets to you the octave thing.
In looser circles/ discussions, we often call noise which is not infinite
in bandwidth or not "flat" in the bandwidth of discussion as "colored" and
when the low frequency end has more than the high, "pink" often creeps into
the vocabulary. "RED" noise would be what many broadcast FM stations seem
to be transmitting now-a-days. 15-20 dB bass boost even on the mics.
Really hard to listen to, but liked by the sub woofer crowd we all hear
coming blocks away.

Source record: 58146

Here's something similar Cecil:

I drove at 65 mph through a limited (about 1 mile wide) wind driven dust storm from an Iowa corn field during a drought. I was watching my S-meter on a 2m radio at the time (in the car). It slowly built up and eventually pinned (simultaneously, AM radio stations suffered the static build up and were blotted out. By the time I got through the mini-dust storm, the PIN diode antenna switching in the 2m radio had been destroyed. It was not raining. It was hot and dry, and you can imagine the dust particle count.

I don't know the mechanics (as you people are disputing), but there was no doubt a significant build up and eventual discharge (I heard it on the AM radio) and the dust in the wind (thankyou Kansas), caused it, IMO.

Another idiosyncratic report:

40m dipole up 30'. Middle of winter, very heavy wet snow.

I could draw an arc off the end of the coax connector about an inch long. The rate of build/up and then discharge (how long it took between SNAPS) correlated very nicely with the rate of snowfall. The harder it snowed, the more rapidly the arc would happen, the more slowly it snowed, the longer in between arcing from the connector.

Both of these, I would call "precip static"...one was dust, the other was snow. I'll leave it to you guys to figure out the mechanism.

Yes, I conncted both top and bottom of the radiator to the previously
floating wire, and when I removed the bottom connection, the SWR bandwidth
remained as before, so the bottom connection does not appear to be
necessary. The top connection is very easy, and evidently that's all you
need, so no doubt about it - - it becomes a Slim-Jim.

I'm old fashioned, so I use an HP17BII calculator which has a "solve" function, and with the formula, LIN = 11811 / F(MHZ) / 4 x VF, given any two of LIN, FMHZ, and FV, I can obtain the third for a 1/4 wave stub.

We find on the Arrow site http://www.arrowantennas.com/j-pole.html the longest element for operation at 146 MHz is 57.5", and the shorter element that makes the 1/4-wave stub is 19.25". With FMHZ = 146 and LIN = 19.25" we solve for VF of that shorter element and get 0.95 (which refers to the free space 1/4-wave as 1.00). Subtracting the 19.25 from 57.5 we get the radiator length of 38.25". Since that is a 1/2-wave length, we divide by 2 so we can use the 1/4-wave formula, and solving for VF we again get 0.95. I hope this helps.

Hasan,

I think the problem here is there are two things at work.

The first is a slow (compared to radio frequencies) build up of charge
in an antenna that eventually breaks down a dielectric. I' like many
people, have seen that many times.
As a matter of fact that is common trigger for relay failures or SWR
detector failures in systems without a leak impedance that leaks off
charge faster than it builds.

The second is what is commonly called P-static. As described earlier
we had severe problems on tall tower and on the roofs of buildings.
This is a noise that starts as a slow rapid hissing or buzzing that
quickly builds almost to a musical tone as the weather gets more
severe. This is the mechanisim I disagree with being caused by
particles striking the antenna. The reason I disagree was clearly
stated:

1.) Taller structures are affected much more than lower ones that are
in the same weather

2.) Even one exposed protruding point seems to be the cause, since I
could cover that point in Station Master antennas and make it go away,
and it would go away by adding a taller blunt ended structure near the
affected antennas.

3.) With identical antennas stacked on a single tower, the uppermost
antenna is by far the most affected.

4.) I could get near the antennas and actually hear the accoustical
noise that matched the noise on repeaters and actually see the corna
ball.

...and on and on.

Cecil then proposed, if I am not mistaken, that P-static was caused by
particles striking the antenna, each one making a noise as it

discharged into the antenna, and that noise could be reduced by grounding the element at DC. That is really the only point I disageed with.

No one should even have a tall antenna or large antenna or any antenna that is subject to high levels of charge that does not have a leakage path to ground. That's just a given. But the idea a closed loop is somehow quieter than an open element that also has a leakage path makes no sense at all (especially when we are talking about noise from each particle) unless the antenna is:

1.) Lower
2.) More blunt
3.) Has less protruding ends

My reasoning is the same number of charges hits each antenna, and the greater the potential difference between those changes and the antenna the greater the discharge power transfer to the antenna will be. So if the antenna were allowed to float to avarage potential of space around the antenna the noise from any energy transfer would actually be less.

This excludes the big pop when a dielectric breaks down.

My mobile antenna is matched by a shunt inductor, and that inductor prevents the coax from charging up with dc. However, that inductor does NOT make the antenna any more useful in weather like you described. It is every bit as noisy, absent the sporatic loud pops when a dielectric breaks down.

Say I leak that antenna with a 20K resistor, and replace that resistor with a nearly zero ohm inductor that has high reactance at the operating frequency. There will be no noise change.

The same applies to repeater antennas. We could use folded dipole elements, elements in fiberglass radomes, and so on. The only thing that helped was a blunter element or making the antenna lower in relation to some other object on the roof.

We looked at dozens of systems hunderds of times, because no one wants communications to vanish in inclement weather. We never found a "dc grounded antenna" any help at all, although some leakage path probably would have stopped the diode failure you had...but not the noise.

Hi Raymond,

If, as you say, the outcome is dimensionless, then your statement

>. the final result for the fractionated gain has unit of ohm square.

reveals not only a conflict, but an error.

The fractional gain is a transfer function reduced from the mesh of 5
impedances and a cold tube shown in Fig. 4.5. Your question above
seems largely out of context to the material.

There was nothing about signals being present in the previous
discussion and this is the first time signals or S/N ratio have
even been mentioned. Signals and/or S/N ratios are therefore
irrelevant to the present discussion.

W8JI previously wrote:

Richard,

There is a focus on evaluating baluns as a passive component in a
bench test jig designed to characterise them by a simple equivalent
circuit to show their imperfections in certain scenarios (eg impedance
range, frequency range, common mode impedance with different balance
points on the load and floating loads). Collectively, we seem to have
done that to death. To date, I don't think anyone has discovered a
practical balun that is close to ideal in all applications.

Baluns (being any device that is designed to facilitate the transition
from un-unbalanced load (might be perfectly balanced, might not be) to
an unbalanced transceiver (one terminal approximately grounded) seem
to be usually employed to:
- reduce common mode RF currents entering the shack where they may
disrupt operation of equipment, and more recently may be a health
concern;
- reduce the feedline's participation in radiation or reception
(pattern distortion, unwanted noise pickup, EMC / proximity to other
equipment).

It seems to me that NEC models are a worthwhile tool in developing
insight into the effects that occur. I think NEC modelling of a coax
fed, centre fed dipole at various heights as a centre fed conductor
with generator at the centre of two wires, and the "third wire" to
ground through some loss resistance is quite revealing. (The coax
example is not to suggest that this phenomena is peculiar to coax feed
alone.)

You mention measuring currents. It seems that discussion on common
mode currents has spawned a new market for clip on RF current probes.

I even see suggestion that common mode current be continuously monitored in much the same way as VSWR is monitored at a spot adjacent to the tx.

NEC modelling reveals that the currents on the "third wire" (common mode current) varies with position (no surprise there), and that depending on the topology, can be insignificantly low at some points while it is significantly high at other points. Measurement of common mode current at just a single point does not necessarily provide enough information to detect or assess a common mode current problem. Spot measurement is a superficial approach.

So if there are maxima and minima in the common mode standing wave current on the feedline, the influence of chokes on current in all parts of the antenna system (hence pattern) and loss of chokes will depend on where they are located.

That is not to suggest that it is all too complicated. I think there are good reasons to routinely deploy baluns of appropriate type an location, but they aren't a cut and dried idealised solution and further work may be required to identify and rectify residual problems.

Owen

Cecil,

When you short ANY transmission line center to ground and the shield is grounded, which is what you asked, ALL signal levels will decrease. They will all go to zero if it is a pefect short.

You have a very strange way of defining noise decreases! If I unplug the receiver or place it on standby, noise will decrease also. So will turning off the RF amplifier. So will adding an attenuator.

If shorting the center to shield making noise go away and ignoring the fact it also makes the signal go away makes you feel like you have proven something, then I can't go further. That's about the silliest thing I've ever heard as a logical arguement!

If the Swr is better below 145 than above the radiator must be over length. You need to trim it or match it. If you are measuring through lot of coax the match at the antenna is a lot worse than 3:1.

Any kind of choke arrangement amounts to working on the wrong problem to me.

3971. antenna coil forms

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-14 03:39:14 UTC
From: rckchp <rckchp@comcast.net>
Message-ID: <1150256354.651203.182360@u72g2000cwu.googlegroups.com>
Source record: 58163

Greetings,

In the course of my occupation I have aquired a bunch of heavy cardboard tubes. These are all 3-1/4" external diameter and approx 1/8 to 3/16" wall thickness. Before sending them to the cardboard recycling dump I though of offering them to the antenna coil experimenters out there. Some of them have what appears to be a plastic coating and would likely be somewhat weather resistant, but even the plain ones could be spray on plastic (or brushed on epoxy or poly resin?) coated. A list how many available and the lengths follows (the plastic coated ones identified with letter "P") :

(2) 32-3/4" P
(2) 24-1/2"
(3) 18-3/4" P
(4) 18-3/4"
(3) 16-1/2"
(6) 15" P
(5) 14-1/4"
(1) 12-3/4" P
(3) 12-1/4
(2) 10-1/2"

I'm offering these free, first come first served, but you pay the postage, or you can pick them up if you're local. I think they can be sent parcel post without any wrapping....I'll just stick a mailing label on them and send them out. When it arrives just look at the postage sticker and reimburse me that amount. Any takers? If so, email me (off list) your name & mailing address.

Tempting, but I'm in pretty good shape here I guess. Also, I'm
kinda wary of any paper material, as it might get damp, etc..
I'm always looking for things to build antennas, coils, etc...
I just stumbled across another recently... I've been thinking
about making a "plastic bugcatcher" for 160m. I already
have two 80-10 versions.. But I always was wondering what
to form a bigger coil on...Well, I think I found one way...
Use these big canisters that DVD's come in... I torch up a lot
of DVD's, and buy a lot of them. Both 50 packs, and 100
packs, that come in the big plastic canisters. I was looking
at one the other day, and thought, *dang*, this would make
a pretty good coil form... They are 5 inches dia, and about
6 inches tall, if you used a 100 pack.. They already have a
spindle running through the middle as an alignment guide..
Some thin sticks might fit as is, but most would need to have
that widened out a bit.. Would be a cinch to rig up..
So I think I'm going to use one of those to wind a 160 coil.
yep, it will be heavy with the wire, and the antenna would have
to be guyed when driving I think. But I could use as is sitting still.
Those canisters could be stacked for more height.
The coil on my 80-10 antenna is 3 inch dia plastic tube, and
the top and bottom caps were peanut butter jar lids. They fit
perfectly. I drilled holes in the caps, and ran the stick up
through the middle, and then glued and sealed it.

Of course I agree when someone shorts the RF input connector of their
radio the noise will decrease! Better yet, they should just unplug it
and throw it in the closet! Then the noise will be zero!

In AZ, I provided a DC path (choke) that eliminated arcing
and allowed me to make contacts. The elimination of arcing
obviously improved my signal to noise ratio.

You have stopped asserting that folding doesn't make for
a quieter antenna system. Do you now understand why a
folded dipole is less noisy than a non-folded dipole in
a charged particle environment?

Do you understand that the probable cause for high
antennas having more particle noise is that the higher
you go, the faster the wind blows?

A few years ago there was a flurry of activity regarding measurement of radiation in the immediate area around the antenna/station. As I recall, anything under 100 watts was exempt from the requirements.

Can someone clarify the situation?

Thanks, jimbo

Hey Jimbo,

Here's a link:

http://www2.arrl.org/news/rfsafety/exposure_regs.html
ARRLWeb: The FCC's New RF-Exposure Regulations

The criteria include both power and frequency, so
powers below 100 watts at VHF and UHF may be
subject to the regulation.

Chuck

Jim;

Go to the ARRL web site. They have links there to the requirements for
power measurement that you are looking for.

Not sure there is information that you want available here, but
http://www.batlabs.com does have a lot of Morotola info. THe HT-1000 is
discussed here: http://www.batlabs.com/visar.html

pretty easy. just buy a beam and some cable, or a vertical / cable setup
from a vendor. it's pretty much plug and play.

if you want to build your own, there are some cool things you can do.

cable *does* matter at UHF. most coax is very lossy.

i'd suggest a stack of long boom Yagis on a 300 foot tower. ;-

Hi Raymond,

This is explained, as a footnote, as an exception to the usage, not
the rule.

>... at the input with the tube (transistor) dead.

Your parenthetic use of transistor is not a valid substitution. Are
you trying to force admittances into this because of your desire to
work with solid state components?

>On my point of view this means (i3/v1) with tube dead multipli by
>(v2/v4)with tube dead and v4 now inserted where the unilateral source
>-W x i3 was before.So the first is propotional to Siemens and the
>second factor is dimensionless.

You now seem to be inventing voltage sources. Bode never uses (lower
case) v and he considers (upper case) V to be an unimportant usage or
concept in his text.

You really need to be more explicit with what you "think" the
co-factors (what you call deltas but are properly determinants) are.

>So as you can see the both factors are dimensionless.

You keep saying that, but this is not math that reduces to one number.
Further, each of the determinants is a complex number. Complex math
rarely reduces to one, real value.

> (I got the 12th reprinting version)

I have the same version.

> , so I guess I
>haven't well understood something.
>Could you tell me your opinion about this .

Bode is very dense material indeed. As I pointed out above, you need
to expand the matrix, then find the co-factors and substitute into the
equations before you start generalizing about admittances. It seems
you are trying to turn Bode into simple algebra - and that is doomed
to failure.

Yes, but there are fewer particles. What, in Yahweh's name, is particle noise? Is it somehow related to the triboelectric effect? What about the effect of the earth's electric field (100 volts/meter)? This is beginning to sound like the Forrest Mims III creation science school of explaining natural phenomena. There are a few articles on what's called "precipitation static" on the web. Generally,it's supposed to be the noise made by corona discharge on objects that have been charged up to high voltages by natural means. You might want to read the articles, Cecil, before you speculate. It could only improve your mind.

If this is a business service radio, I'd imagine most Motorola or
business radio dealers would have a "base station" type of antenna you
could hook to the walkie talkie with the proper cable and connector.

>May you tell me what it's the physical significance in this example for
>these relations ?

Hi Raymond,

You alternate between questions of math and physical significance. The two are linked only through abstractions at this point in the discussion.

The "relations" appear to be math for combined series and parallel combinations of the impedances. Others may wish to examine the math at the end of this posting.

>--- Yes I keep saying that, imagine Z1 ,Z2 ,Z3 ,Z4, and Z5 are pure
>resistors (so it's means Witout =3Dw/o parasitic elements) the (5-20)
>result holds so it's means the first factor Z2 /Z1+Z2+Z3(.../...)
>coresponding to delta(1,3)/delta^0 is dimensionless.

If the matrix is entirely resistances, then a co-factor must be resistances. How did it become dimensionless?

>I have done the calcul and I found 1/(Z1+Z2+Z3(../..) instead of the
>Bode one

This doesn't make much sense - show your work.

>so it's means the same result w/o the Z2 , for the second
>member same result but w/o the multiplicative factor Z4.

This makes even less sense - show your work.

Aside from that, and relating to only one point you complained of - admittance. Look at the last term of (5-20) and note that it is W. W is an immittance. An immittance is normally dimensionless, but in older texts it can be either an admittance or an impedance depending upon context.

********** Fixed Font **********

For other's benefits, the circuit is simplified by Bode to:

```
------- Z2 -------- Z4 ------
| | |
Z1 Z3 Z5
| | |
----------------------------
```

Fractional gain = - term1 ï¿½ term2 ï¿½ Z5 ï¿½ W

where

term1 = Z2

```
-----------------------
Z3(Z4 + Z5)
Z1 + Z2 + ------------
Z3 + Z4 + Z5
```

term2 = Z4

```
-----------------------
(Z1 + Z2)Z3
------------- + Z4 + Z5
Z1 + Z2 + Z3
```

and

Z1: source Z
Z2: grid-cathode parasitic Z
Z3: cathode circuit Z
Z4: cathode-plate parasitic Z
Z5: load Z

I don't think that is true. Dust is sucked high into the air during the formation of a dust storm. I have seen a wall of dust hundreds of feet high in Arizona. It didn't look any denser closer to the ground. In any case, it is not the number of particles that matter but the average charge per particle which increases with wind speed.

From what I remember, that's not universally incorrect.

Oh, and I'm taking your apostrophe quiz, and it appears there's an error
in the "correct" choice: (B) uses "its" as the contraction for "it is".
So the answer to 17 should be "None of the above". (I scored 100% also.)

Incidental note: I've never understood how people who use "it's" as a
possessive never even think to use "hi's" (though some use "her's" and
"their's").

I'd suggest you comply with the rules. It's easy and more than likely
you will pass muster. I used this site for my evaluation:

http://n5xu.ae.utexas.edu/

I also made copies of my antenna specs and attached them to the report,
then filed.

Modernizing ham radio:

No more CW, easier to pass written exams. We Should change the names: Tech, General & Extra too. No sense hanging with the dinosaurs when there's no need to be proficient at anything anymore:

Appliance Operator 1st Class, Appliance Operator 2nd Class

Appliance Operator 3rd Class, No Class

Now Ten twenty-seven to channel one nine to get a preview of the new classes. I'm ten seven. Any one got a ten thirty-six hello.

Sorry for the CB lingo, I'm just getting practiced up so I can understand people when the CW test goes away.

You really want modernization?

It probably comes from charged particles and the earth's
electric field, but you won't know anything for sure unless
you can come up with a mechanism for showing how dust particles
get their charge in the first place. Then you have to measure
it. In some old issue of Scientific American there's an article
showing how to make a simple gadget to measure the electric
charge on a raindrop (about .3 volt, average). I expect you
could use the same idea to measure the charge on a dust particle
during a dust storm. Then you'd have to calculate. That shouldn't be
too hard for you to do, Cecil, you're an engineer.

Sure I want modernization. I dont have to put up with any of it. I havent been on the air for at least ten years. I renewed the license, then put it away.
The ham bands are gonna go away, and soon. They are gonna go the same way that respect for your fellow amateur went, cooperation went, etc. The FCC has a vested interest in shutting the ham bands down, since their funding got cut years ago. BPL looked like a winning plan to shut it all down so they could sell it off, but that flopped, since it also interfered with other emergency services, like police and fire. so, the easiest way to shut it down for good is to just hand it over to the cb crowd. They will make a complete mess out of it, and they wont waste any time doing it, either.

Then the FCC can improve their funding, considerably. Just think, the fines from the violations alone will come to millions. Did you really think that the FCC was looking for "new innovations and inventions" coming out of ham radio ? This is the digital age, guy.
In the meantime, enjoy these tirades from folks about the "fat-amateur". Me, I pump iron every day, and could probably knock most of them on their keester without even breaking a sweat, and im twice their age. The irony of them opening their mouths has not escaped me, these new, modern "sensitive" guys that are doing 99% of the ranting on this subject. It begs the question: Just which pair of their mother's panties are they wearing today ?
Ham Radio started to suck about ten years ago, and it is going to continue the downhill slide. Get tused to it.

And before you start in on me, lemme tell ya fella, i was a cw operator, and i also built most of my own stuff. It just ain't worth it any more. Period.

OOPS , tis a SMA FEMALE connector you want! (this
also works for signal generator/wattmeter) to a
(BNC/or UHF) adaptor ! About $10 bux for high
quality, but maybe cheaper for the nickel plated
variety -- Jim

When I was working on repeater systems trying to figure out how to make an omnidirectional antenna (mounted ABOVE the tower or mounted above other things on a roof) not get wiped out by p-static I talked to an person at NASA who delt with problems NASA had.

I've forgotten most of the numbers he quoted for electric field intensity as height increased and the effects of things that modified the impedance of that voltage, but I left those conversations and the experiences with an entirely different view than when I entered.

Moving the antenna just a few feet lower than other objects made a large difference in p-static, and that was at heights between 200 and 800 feet above ground.

It's a nice guess by Cecil that there is less wind or less particles at 180 feet rather than 200, or 780 feet rather than 800 AGL, but in real life there probably isn't much difference.

When people spend a few thousand bucks changing to dc grounded antennas, antennas in radomes (Super Stationmasters) with only a metal tip exposed, and folded dipoles... only to find the only thing that helps is making the antenna NOT the tallest or most protruding point....it's tough to accept something that didn't ever make a difference.

Of course if I viewed the world through a 80 meter dipole at 50 feet with only dust to worry about and never talked to the fellow at NASA, or if I never had multiple antennas on multiple tall towers or worked on all those commercial systems, I might agree with Cecil.

All the problems I saw related to corona.

73 Tom

I doubt that the CBer would take over on all bands. One of the attractions
of CB is the cost of equipment. The FCC will probably sell off the unused
bandwidths to private organizations such as cell companies and repeaters for
the service industry to name a few. They can then be done with all the
headaches with ham/cb enforcement and concentrate on other, more lucrative
areas, such as Janet Jackson's half time nipple exposure.

I thought I had a coax problem. Every time I tried to check the dc resistance of a length of coax not connected to anything, I always got a reading around 1.25 meg. This is not a short nor open line so I checked another length and got similar results, so I was really baffled. The odd thing is that both of these coaxes work perfectly when connected to an antenna. I finally found out what I was doing wrong. I was using probes that I had to hold with my fingers, so I was really measuring the dc resistance between my fingers. After watching my fingers, I get infinite dc resistance like I should. This one really baffled me for some time, I don't wish something like that to happen again.

When the only tool one has is a corona hammer, all problems
look like corona nails. Fortunately, I am familiar with both
corona problems and dry-air wind-driven charged particle
problems.

> All the problems I saw related to corona.

At least that's what you assumed. Just because all the cars
parked in your driveway are white doesn't mean all the cars
in the world are white.

Whether it's dust, snow, or the atmospheric electric field charging the antenna, the noise is still corona discharge. At least that's what most of the sources say. Tom says height makes all the difference. That would make a lot of sense given the way the earth's electric field is structured.

The argument is not what it is called. The argument is whether
charged dry-air dust particles can transfer charge to bare-wire
antennas.

Man, you guys really crack me up. I must admit I kinda enjoy reading
your posts, though.

\There must be some source citing experimental evidence of charged
particles in a dust storm transferring their charges to a collector of
some sort (antenna). I alluded earlier to a practical use of such
collection...
Cecil, you said you have no idea how many Joules were represented (or
something along those lines).

Seems to me, that Joules per unit time is precisely the measure that's
needed in this "analysis". Is this Voltage, or am I mistaken?

Compare the density of the dust cloud with the charge collected. There
should be a correlation. What about velocity of the cloud: more charges
transferred per unit time.

If your rug was scorched, some "work" was done. My college physiscs is
only a nightmare away: what is the relation of Joules to work?

What was the other issue: number of particles versus the charge per
particle? Got me.

As the particles are swept off the surface of the desert, would their
charge (per particle) be distributed (as Gauss or some other)?

I would think the # particles would be more important.

If a given volume of dust particles moves through the field of an
antenna (it would have a field, wouldn't it? ... even if grounded?
perhaps field is the wrong word), increasing velocity of the volume
would mean more particles per unit time passing the antenna. Hence more
charge transferred: more charge per unit time. Again, is this Voltage?

I guess I can't part with my trickle charger idea.

You guys have at it. Thanks for letting me butt in.

John

Of course if it WAS a megohm shunt at the operating frequency, you wouldn't even notice it. But yes, your advice goes equally for other resistance checks. Don't expect to evaluate even a 10k resistor accurately by holding the test leads on it with your fingers. I have some voltmeter test leads with "grabber" hooks that I just love for things like that--these particular ones have points that work like regular probes too.

If you really do want to check the coax's high resistance with your fingers, charge up a 30 meter or so length to about a kilovolt, let it rest with no applied voltage for several minutes, and see if it will "zap" you when you touch across the conductors. If you're crazy enough to try it, do NOT do it with two hands, because there's some danger with the current going through your upper body... If the line stays charged to, say, 9/10 of the original voltage for an hour, what resistance is that? Well, it would be roughly a ten hour time constant, and if it's 50-ohm line with solid polyethylene dielectric, it will be about 3000pF capacitance, so the resistance would be about 10^13 ohms. Don't be surprised if it's actually better than that, even...I have a couple metalized polypropylene caps I charged up a few years ago that I take out and measure every once in a while (very carefully with a very high impedance volt meter), and they are showing a self-discharge time constant in excess of 50 YEARS.

Cheers,
Tom

Joules (energy) per unit time is power, not voltage.
>
> Compare the density of the dust cloud with the charge collected. There
> should be a correlation. What about velocity of the cloud: more charges
> transferred per unit time.

Charge per unit time is current.

> If your rug was scorched, some "work" was done. My college physiscs is
> only a nightmare away: what is the relation of Joules to work?

The joule is a unit of energy. Work is energy, so it can also be
expressed in joules.

> . . .
> If a given volume of dust particles moves through the field of an
> antenna (it would have a field, wouldn't it? ... even if grounded?

An antenna creates an electrostatic field if charged, but an
electromagnetic field only if that charge is being accelerated, that is,
if it carries current which changes with time.

> perhaps field is the wrong word), increasing velocity of the volume
> would mean more particles per unit time passing the antenna. Hence more
> charge transferred: more charge per unit time. Again, is this Voltage?

No, charge per unit time is current.

>. . .

It's impossible to contribute much to the understanding of complex
phenomena without first gaining an understanding of the most basic
principles.

> of the sources say.

It is my understanding that the air around a conductor must
ionize for it to be defined as corona. Obviously, there is
a time when charge is transferred to the antenna before
ionization (corona) occurs. Corona is defined as a discharge
function. The charging function must necessarily occur before
corona. If the charge is not allowed to accumulate up to the
ionization level, corona will not occur, by definition.
Precipitation static occurs before the corona threshold is
reached. For what it's worth, here's what the 2000 ARRL
Handbook says:

"Precipitation Static and Corona Discharge"

"Precipitation static is an almost continuous hash-type noise
that often accompanies various kinds of precipitation, including
snowfall. Precipitation static is caused by rain drops, snowflakes
or even *wind-blown dust*, transferring a small electrical charge
on contact with an antenna."

"Electrical fields under thunderstorms are sufficient to place
many objects such as trees, hair and antennas, into corona
discharge."

Although not stated explicitly, seems to me there is a strong
implication that precipitation static is not strong enough to
ionize the air, i.e. not strong enough to cause corona to exist.
Indeed, the arcing at a coax connector or the DC grounding of
an antenna may be enough to prevent ionization and corona
during a precipitation static episode.

>
> If the matrix is entirely resistances, then a co-factor must be
> resistances. How did it become dimensionless?
>

********** the determinant Delta itselt makes no sense for unit. but
not the ratio of cofactor and determinant,
i can say that : if the unit of all element of matrix is ohm, assume

matrix is of Nth order ,
then is determinant's unit will be ohm^N, and first ordre cofactor
[delta(x,y)] will have a unit of ohm^N-1, so the ratio will have a unit
of ohm or siemens (depends on cofactor is in Numerator or Denominator)

so cofactor is not simplely a resistance here.

> >I have done the calcul and I found 1/(Z1+Z2+Z3(../..) instead of the

> upon context.
>
>

********* I think Immittance is not dimensionless, because it must be
an impedance or an admittance, so it will have a unit of ohm or
siemens. if not, could you tell me what's an immttance for the modern
texts, if it doesn't represent impedance or admittance.

> *************** Fixed Font ****************************

> where
> term1 = Z2
> -----------------------
> Z3(Z4 + Z5)
> Z1 + Z2 + -----------------
> Z3 + Z4 + Z5
>

In Page 81, Bode said this term can be recognized as the
Delta(1,3)/Delta(0), but as i discussed above, the ratio must have a
unit of ohm or siemens. (depends on mesh or nodal equations)

but if we examined this term, it's dimensionless.(for simple, we can
assume all impendance only have real part, it means only resistive)

so there's a paradox with bode's words.

> term2 = Z4
> ----------------------
> (Z1 + Z2)Z3
> ------------- + Z4 + Z5

>

********** the same problem

> and
> Z1: source Z
> Z2: grid-cathode parasitic Z
> Z3: cathode circuit Z
> Z4: cathode-plate parasitic Z
> Z5: load Z
>

At last, W is an immittance in bode's book, in mesh analysis, W is an
impedance and in nodal analysis it's an admittance.
Here what do you think about W (impedance or admittance)for Frational
gain.

Thanks!

No; in fact, I live near Seattle! It might actually be worse in a hot desert, though, because the leakage probably doubles every 10C or so. Mine are stored with one lead soldered to a PC board, and the outher up in the air, in a little cardbaord box. Of course, the gates in isolated-gate PROMS hold their charge a very long time, too. But modern automated manufacturing in well controlled processes produces some very consistent materials. I told Bob Pease about my capacitor 'speriment (with two polyester = Mylar caps, and two polypropylene, all 0.1uF, all initially charged to about 12V, the limit of my high-impedance volt meter) and he told me about being surprised that an unplugged common printer power supply he had held its charge for many days. I can tell you that the Mylars have a self discharge time constant (about 5-10 years) about 1/10 that of the polyprops. The "supercaps" aren't too bad either--those 1F 5.5V things. Seems to me I measured a few months for those, though I don't remember for sure right now.

Way off topic for antennas. Sorry, but some may find it interesting anyway.

Cheers,
Tom

There was once an article in the old Scientific American Amateur
Scientist section about using the earth's electric field to
power various static electric motors. Just build a motor from
one of the simple designs on the web; using a weather balloon,
run a wire up 300 feet or so (should give you 9000 volts or
so on a clear day); attach your motor between the wire and ground, and,
once the wire charges up, the motor turns. You won't get much work
out of it, but it'll run a long time.

Cecil, you can do a web search for "precipitation static," and
"Saint Elmo's fire," to find out what most people think
precipitation static is. Before I'd believe that each little
raindrop makes a noise as it strikes the antenna, I'd want to
see an experiment showing this. Most of the sources on the

web, at least, don't mention it, but generally agree with Tom about the cause of the problem. You can read all that for yourself.

It's only raindrops having a charge different from
the antenna that make the noise and I have previously
explained the mechanism of charge equalization between
the two dipole elements through the link.

Seems to me only magical thinking would result in each
and every raindrop having a charge exactly equal to the
antenna upon which it is falling. I'd like to see you
come up with a proof for such an assertion.

> Most of the sources on the
> web, at least, don't mention it, but generally agree with
> Tom about the cause of the problem. You can read all that
> for yourself.

I have read it for myself and *nothing* I have read agrees
with W8JI. Corona doesn't exist until ionization takes
place. Precipitation static and even arcing do not require
any corona to exist. Here's a web page that explains the
difference between arcing and corona discharge including
a gray area called "brush discharges".

http://www.ce-mag.com/archive/1999/novdec/mrstatic.html

Please notice that arcing at a coax connector doesn't require
corona at all.

Hi Raymond,

That is what I said.

>and if you read Bode's book, you can feel that he
>always explain the physical meanings of his math equations and symbols.
>such as Delta(x,y)/Delta(0)
>(Delta(x,y) is the cofactor of determinant Delta)

And that too, has been said. Bode has developed what is a transfer
function. That is the math. He has developed it from the conditions
of a tube circuit in which the tube is unpowered. That is the
physical meaning. The two are abstractly linked. That is the lesson.

>so cofactor is not simplely a resistance here.

The matrix assignment of all resistances replacing complex impedances
was YOUR stipulation, how a co-factor does not resolve to resistance
is your error. I expect you to fully demonstrate your own example,
not assert a conflicting conclusion.

You have not yet fulfilled:
>> This doesn't make much sense - show your work.
>> This makes even less sense - show your work.

>> Aside from that, and relating to only one point you complained of -
>> admittance. Look at the last term of (5-20) and note that it is W. W

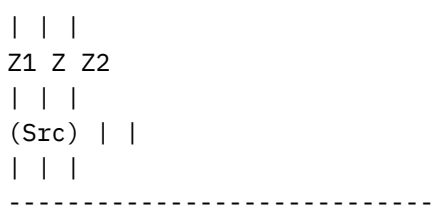
>assume all impendance only have real part, it means only resistive)
>
>so there's a paradox with bode's words.

Your problem with this subset of equation 5-20 suggests you skipped over earlier work. There is no paradox. The subset above is developed identically to equation 4-17. If you could achieve it, then equation 5-20 is no more problematic.

********** Fixed Font ****************************

For other's benefits, the circuit provided by Bode for 4-17:



where equation 4-17 is

$$\text{gain} = \frac{Z}{Z1\ \text{ï¿½}\ Z2 + Z(Z1 + Z2)}$$

No, I think it is up to you to prove that each and every
raindrop that falls has exactly the same charge as
any antenna upon which it might fall. Which means that
you must prove that all antennas being rained upon have
identical unchanging charges. That is what would have to
be true for you to be correct. Sorry Tom, please peddle
your magical thinking to someone else. What do you think
about the 2000 ARRL Handbook quote?

"Precipitation static is an almost continuous hash-type noise
that often accompanies various kinds of precipitation, including
snowfall. Precipitation static is caused by rain drops, snowflakes
or even wind-blown dust, transferring a small electrical charge
on contact with an antenna."

The physics of charged particles has been understood for
a century or so. I am not going to waste my time proving
those known and accepted facts of physics. It is up to you
and W8JI to prove a century of physics knowledge to be
wrong. Good luck on proving that all static is caused by
corona discharge even in the absence of the necessary
ionization that defines the word "corona".

4046. Antenna Q as a useful measurement

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-15 18:51:24 UTC
From: "n3ox.dan@gmail.com" <n3ox.dan@gmail.com>
Message-ID: <1150397484.025443.139030@f6g2000cwb.googlegroups.com>
Source record: 57838

I'm wondering about calculating antenna efficiency from the Q as measured at the feedpoint.

I know the definition of antenna Q has been hashed out a bit on this group, so let me be specific and say that I'm measuring Q by looking at the half power bandwidth around resonance as I would with an LCR circuit, or maybe I'm looking at the generalization for a different voltage down from the maximum, so I can use the 2:1 SWR bandwidth as per the description here:

http://lists.contesting.com/_amps/2006-01/msg00179.html

Once you know the Q, you need to know the antenna's radiation resistance using some method, so that you can figure out the loss resistance.

Is seems reasonable to model the antenna in EZNEC with lossless elements and use the feedpoint resistance at resonance as the radiation resistance and then subtract that off from the R calculated from Q=X/R.

Then all the loss elements are empirically determined, ground losses, bolted connections, traps, etc etc.

Any comments on this? It seems a good idea to me but I'd welcome some holes poked in it. I know that accurately modeling things like multiband verticals and so forth even in the lossless case might be tricky.

Hi Dan,

Conceptually close, but certainly not to the degree of accuracy you
might expect. 2:1 SWR points are not half power, as would be the
classic determinant for Q bandwidth. As your link provides, it is 88%
power points.

Source record: 57842

Yes, I guess alternatively you could calculate the SWR at the
half-power points from

(E/Eo)^2=(1-((1-SWR)/(1+SWR))^2)

With E/Eo = 1/sqrt(2)

I get that this is about SWR = 5.8, and I understand that the MFJ-259B
is less and less accurate as the load moves away from 50 ohms
resistive, so it might be better to use the 88% power, 2:1 SWR
bandwidth points.

- - - - - -

I've thought of an additional question regarding this method. The
ground has an effect on antenna feedpoint impedance. This effect
contains both modification to the radiation resistance and the loss
resistance components of the feedpoint resistance.

Is the effect on the radiation resistance different for lossy earth and
for perfect earth? Obviously the loss increases with proximity to
ground, but can the effect of ground reflections on radiation
resistance be accurately modeled by putting the antenna over perfect
ground?

I think you miss the whole point Cecil.

1.) It isn't the noise made by the actual contact of particle to the antenna that makes what is commonly called p-static noise. There are many ways to disprove that through direct observation, and I have done that many many times. The problem is largely caused by the potential difference between the antenna and the area around the antenna, which is what causes corona.

This is why on days when there are clouds with high levels of charge from approaching storms there is p-static, even when no particles are strinking the antenna, there is noise.

This is why the noise level is higher and appears earlier on taller antennas, and why lowering the antenna SLIGHTLY in height but noticably below other structures greatly reduces or eliminates noise. It's also why a Super Stationmaster, in a fiberglass housing with the internal element spaced away from the housing BUT with a small metal tip out the top, has about the same noise level as a bare element.

We spent thousands of dollars changing antennas based on the common myth (which at one point in the 70's I swallowed like you are today) that it was the contact of particles to the antenna that caused the noise, money I wish I could have gotten back.

You tend to toss out anything that disagrees with you.

2.) No one is disputing how particles behave, except perhaps those who think the particle contact noise is the problem and that providing a dc path somehow eliminates that energy transfer.

You're the one who made the statements, Cecil, so you're the one
who has to prove them. Just tell me how you sprayed charged
water drops on your antenna and recorded the noise from your
receiver when each one of them hit. If you can't do that, all
appeals to a higher authority are meaningless.

Hi Richard,

Just for 4-17, if you read the phrase just before the 4-17. you can
find that
the gain is the current in response to the unit generator (1V voltage
source),
so it's clear that result 4-17 is transfer admittance I/V. Here we
omited the load Wr.

on the contrary, in 5-20, the load impendance Wr has been taken as Z5.
so i can't see any relevance to our question.

Thanks,

SWR bandwidth is pretty much meaningless in this effort. If you model
the antenna and then use the reactance slope with respect to frequency
around the resonant frequency then you can calculate an equivalent L &
C for the radiator. With this and the feedpoint resistance you can
calculate Q, for whatever it's worth.

Close to resonance the reactance slope is very near linear and the
real part is nearly constant. I use Excel's solver to find L & C and
go from there. With coupled elements (Yagis, etc) I'm not sure this
method is particularly useful, but I'm not sure whether knowing the Q
is very useful in the first instance.

Assuming that "p-static" is precipitation static, you already
agreed with the laws of physics that make your statement false.
Any particle with a charge different from the antenna wire
will cause particle noise even when the corona threshold
is not even close. There's no way to stop a charged particle
from transferring its charge to a bare-wire antenna. There's
no way to keep that charge from equalizing through the
link coupling in a non-folded dipole. This is all easily proved
using very small charges nowhere near the corona threshold.

I agree that some cars are white. I just disagree with your
assertion that all cars are white. I agree with the 2000
ARRL Handbook about precipitation static Vs corona static.

> The 2000 ARRL Handbook says:

I also agree with what they say about corona static which certainly
exists and is what you are talking about. But corona static is not
the only thing that exists, as you are asserting.

Hi Raymond,

OK, so I see partial solutions for parallel and series impedances.
They are all quite in agreement with Bode's equation 5-20 - in
general.

However, the computation of i1 on page 3 entirely omits Z2. As a
result, the co-factored computation does not agree with the solution
found on page 2. del0 also omits Z2.

If page 3 were to agree with page 2; then it would seem that your
matrix substitution for del13 to del11 should have a equal treatment
for Bode's del42. It would appear he has at least one more mesh than
your analysis.

In this regard, it would pay to work backwards from equation 5-20 to
chapter 1 where the larger matrix resides for all the discussion up to
this point. This comes from the treatment of figure 1.5 which
contains the same number of impedances, but is treated with a larger
matrix. Observe how the meshes are defined and consider how he
implies the same treatment for figure 4.5.

Bode also offers advice on mesh vs. nodal analysis in chapter 1 (page
16) that bears upon your wish for physical correlation. Make sure to
heed his warning about the virtues of nodal analysis and what appear
to be your difficulties with mesh descriptions.

Wes and Richard. I've realized my conceptual mistake here. I have an antenna analyzer, not just an SWR meter. I can MEASURE the resistive part of the feedpoint impedance. I can calculate the radiation resistance using EZNEC or more simply for simpler antennas.

The resitive part of the feedpoint impedance minus the radiation resistance is the loss resistance, and then I can calculate the antenna efficiency.

I've complicated things by getting the Q involved, though maybe if all you have is an SWR meter...

Thanks for the replies.

73,
Dan

Hi Dan,

To say the least.

>This effect
>contains both modification to the radiation resistance and the loss
>resistance components of the feedpoint resistance.

Well, it doesn't change radiation resistance, that is a property of
the height of the radiator (as in length, not how high above ground).
As for feedpoint resistance, the loss of ground is cast into the
determination of feedpoint Z (which contains the sum of Rr, Ohmic loss
of the structure, and dielectric loss of the soil).

>Is the effect on the radiation resistance different for lossy earth and
>for perfect earth?

To say the least.

>Obviously the loss increases with proximity to
>ground, but can the effect of ground reflections on radiation
>resistance be accurately modeled by putting the antenna over perfect
>ground?

Ground reflections are post-hoc determinations of what happens to the
available power AFTER it has escaped ground loss and left the
radiator. Ground serves to influence the radiation pattern, but only
ground at a distance. This is basically ray-tracing and trigonometry
between the antenna as a point, and the far field earth. Ground also
serves to influence the radiation pattern insofar as how much power is
divided between heating the ground and radiating out to that ground at
a distance which then bounces off and away.

Perfect ground has no loss, and is perfectly reflective. Poor ground
(very poor ground in fact) has little loss, but little reflectivity.
Better ground has more loss, but higher reflectivity. Ground is a
two-edged sword and the degrees of variation don't swing very far for
the majority of Hams.

If you happen to be one of those minority Hams, you possibly have your
vertical planted into very low loss sand dune overlooking the ocean.
If you happen to reside at the other end of the bell curve, that

minority probably lives in a mountain valley swamp.

All situations bear upon the drivepoint Z, and the launch characteristics, but bear in mind they are separate characteristics that have different major variables.

Ha, ha! Nice joke, Cecil. I'll tell you what: if you can show that a group of students can tell whether it's raining or not solely by listening to the static on a radio with an outside antenna, I might begin to believe part of what you say. Otherwise, all your talk about carefully selected references is little more than a pathetically hollow attempt at self justification.
73,
Tom Donaly, KA6RUH

(P.S. You'll have to figure out a way to get rid of any charge buildup in order to keep the corona noise at bay.)

Q cannot be measured. It is a dimensionless number. It is merely a ratio of two quantities which ARE measurable.

But it's not so ridiculous as measuring the standing wave ratio on an imaginary transmission line.

It especially shows up in the 300 inches a year lake effect snowfalls in northern NY. You can hear it on 6 and 2 quite well. These were DC grounded yagi antennas on all elements, so no corona available here, thank you.

Also, K1RQG, who is net control of the EMENet on 14345 Sat and Sun mornings, had it so bad from rain last weekend that he couldn't copy most of the participants for a few minutes. And in a heavy rainstorm, I have doubts that it had much to do with corona.

Thanks, Tom, for your reasonable response. So, I guess we're talking
lots of voltage and very little current...makes sense.
Wasn't Ben Franklin involved in working all this out?

I'll ask another question that no doubt is off the mark:

The Santa Ana winds in California are supposed to blow for long periods
of time. Are there any measures of voltage, current, joules or cole
slaw on antennas in this area? Do they experience the "noise"?
Couldn't one connect a large capacitor circuit to store the charge and
trickle it to a battery?

(I just won't give up, eh?)

What makes you think the charge gradient and corona goes away with a grounded element? Because there is never lightning and lightning never hits a grounded object? Where dod you get that idea?

The earth is one terminal, the air and things in the air (like clouds) have a charge difference.

Since the "sky" is one terminal and the earth the other with large charge differential, why would you think connecting a tall sructure to earth REDUCES the charge differential?

> Also, K1RQG, who is net control of the EMENet on 14345 Sat and Sun
> mornings, had it so bad from rain last weekend that he couldn't copy

> have doubts that it had much to do with corona.

Why? Maybe you can answer this.....

Do we have more lightning, which is caused by a charge difference between clouds and earth so severe it actually arcs for thousands of feet, in heavy rain or on clear dry days?

Do the leaders and streamers form on clear dry days, or when the weather is nasty?

You have it exactly backwards Tom. Grounding the element doesn't reduce corna or reduce the charge difference between air and things in air around the element and the element, it INCREASES the difference. If we could float the element and allow the element to charge to the potential of things around the element, the voltage gradient between the element and things around the element would be reduced. Why do you think the element, if we float the feedline, arcs to earth? It does that because the air around the element is greatly different in potential than the earth.

As for moisture, you also might do another test. Blow gently on a CRT anode lead. See if your hot humid breath increases corona or decreases it. Now go get a Windex bottle full of water and spray a mist on the anode lead and see if the corna goes away, or gets worse.

I wonder how many people really understand there is a huge potential difference between the air and earth even on a calm clear day, and

nasty weather can just make it worse.

You'll get a lot more energy out of the wind by just putting up a wind
generator. There are many wind farms in California.

So this is an inverse form of corona? Where it comes from the surrounding charged air and particles (whatever type they are)? Because it's not the form I'm familiar with where the end of the antenna has a high voltage on it.

I am genuinely asking a question here. If this is the way that noise occurs, I'd like to know the physical method involved.

It still sounds like it matches the description of what is commonly called precipitation static, and it still makes a lot of noise, unless you'd like me to disbelieve my lieing ears.

In Arizona, we have the worst precipitation static on clear dry
days without a cloud in sight. You have just made my argument.

> Do the leaders and streamers form on clear dry days, or when the

If corona requires clouds, you have lost the argument.

If it's not enough to cause ionization, it is NOT corona,
by definition. The charge buildup before a corona discharge
is NOT corona. If the charge doesn't result in ionization,
it is not corona.

Quoting the 2000 ARRL Handbook: "Electrical fields under
thunderstorms are sufficient to place many objects such
as trees, hair, and antennas, into corona discharge."

Of course, corona discharge exists and grounding an antenna
might make it worse. But corona discharge is not all that
exists.

And in the absence of clouds, corona discharge is not
likely to exist. Some other mechanism is obviously
responsible for clear-sky charged-particle static.

Yup, me too. I listen to "A Way With Words," a radio program on KPBS
(available streaming at kpbs.org) whose host is language writer Richard
Lederer ("Anguished English," "Get Thee To A Punnery," etc). Richard said
that "it's" for "its" (possessive) was considered correct until near the end
of the 19th century. I didn't know that.

==========

About 20 years ago I measured the charge produced on a 150-feet, long-wire, end-fed inverted-L antenna, using a DC, 0 to 50 micro-amp, moving coil meter.

It was a warm afternoon. Temperature about 25 degrees C. There was a clear-blue, cloudless sky with a dry breeze. I assume very low atmospheric humidity otherwise the charge would leaked away over the antenna's insulators.

There was a 300pF receiving-type, air-spaced tuning capacitor in series with the antenna. The other side of the capacitor was grounded via the transceiver which was not switched on.

Every few seconds the capacitor was breaking down with an audible click. I could not see a spark. The plates were spaced about 1mm apart. It was the clicks which drew my attention to what was going on. The clicks slowly varied at a rate of 1 every few seconds to as many as 5 or 6 per second.

I removed the capacitor and grounded the antenna through the micro-ammeter. The current varied around 10 to 20 microamps. After 5 or 10 minutes the effect gradually died away.

I can't remember the current polarity. The transceiver had not been damaged.

While making the connections with un-insulated aligator clips I received one or two mild shocks. All for the sake of science!

Later on in the day, clouds built up and there was a thunder and rain storm. Electricity had been in the air all along. How it got there I can't imagine except that it may have been due to the friction of dry air blowing past the antenna wire.

There was no precipitation unless it was plant pollen in the air. I don't suffer from hay fever or asthma.

Reg, G4FGQ

Some 19th century doctors scoffed at the idea that there
could be germs so small that they could see them. :-)
Dust particles come in all sizes. Run some clear air
through a HEPA (High Efficiency Particulate Air) filter
and see what you get.

There are always particles in the air. Sometimes they
carry a charge. Air itself, is made up of particles.
Quantum Electrodynamics tells us that charge transfer is
impossible without particles.

For Tom^2 to be correct, every dust particle that touches
every antenna would have to carry the same identical charge
as the antenna to keep charge from transferring. I would
sure like to see them prove that assertion.

I don't understand that Tom.

What is "inverse corona"?

Corona comes from a charge difference between two things. In this case it is NOT a charge difference between the earth and the antenna that you could eliminate by shorting the antenna to the earth, it is a difference between the air around the antenna and the earth and things connected to earth. The corona is leaping off into space around the antenna, not back towards earth. Tying it to earth will only make it worse, not better.

> I am genuinely asking a question here. If this is the way that noise
> occurs, I'd like to know the physical method involved.

In every case I have looked at, and I have looked at dozens very carefully, it has been corna off the elements. That corna (and the resulting noise) occurs when there are particles, when there aren't, and at a rate different than the rate of particles hitting the antenna.

It occurs with radomes and insulated elements and without, it occurs with grounded elements and without.

It increases with increasing height, especially compared to surrounding objects. It is worse with protruding sharp points on the elements.

It is worse when the charge difference between earth and sky is greatest, and less when the charge difference is less. It is terrible when lightning is almost ready to strike. It often vanishes totally for a brief period after a ground to cloud lightning strike.

Of course a book, especially a handbook, might say it is something else. But then what they say should fit what occurs most of the time if what they say is mostly true.

In my experience, and I probably have much more than most people with this after changing dozens of antennas to try to eliminate this

problem, the idea the noise comes from an element "charging" or from particles hitting the antenna is largely incorrect.

I think that idea comes from reading and believing wive's tales and rumors, and not thinking and experimenting for oneself.

Cecil,

I am not entering this debate one way or the other. I do have a
question, however.

How do you determine when the ionization threshold has been reached?

73,
Gene

w8ji@akorn.net wrote:
> Corona comes from a charge difference between two things.

No, that's not complete. A charge difference is necessary
but not sufficient to cause corona. Corona comes from a charge
difference between two things that causes ionization of the air
around/between the two things. Corona, in the electrical sense
that we are using the word here, doesn't exist and cannot exist
without ionization. For this definition of the word, "corona",
my unabridged dictionary says, "7. Electrical: see corona
discharge".

In the web reference I posted yesterday, two charged spheres
arced before any corona was possible. Corona never existed
in that experiment even though arcing took place.

> In every case I have looked at, and I have looked at dozens very

Certainly white cars exist. That doesn't mean that all cars
are white.

> It occurs with radomes and insulated elements and without, it occurs
> with grounded elements and without.

Certainly corona exists. That doesn't mean the entire universe
is ruled by some Corona God.

> It increases with increasing height, especially compared to surrounding
> objects. It is worse with protruding sharp points on the elements.

For it to be defined as corona, it must ionize the air. How do
you prove that the air has indeed been ionized? At night, a
glow invariably accompanies corona ionization. Do your antennas
glow at night? Mine usually don't.

> It is worse when the charge difference between earth and sky is
> greatest, and less when the charge difference is less. It is terrible

"It" being corona, not clear-sky, dry-air, charged-particle
problems. Everyone agrees that corona exists, Tom. We just
disagree with you that corona is all that can cause a charge.
Is the 10 volt charge on a capacitor caused by corona?

> Of course a book, especially a handbook, might say it is something
> else. But then what they say should fit what occurs most of the time if
> what they say is mostly true.

Most of the time doesn't cut it, Tom. All it takes is one
example to the contrary to prove your all-inclusive assertions
to be false. Not all cars are white just because you have never
seen a colored car.

> particles hitting the antenna is largely incorrect.

That may be true, but the question is: Do charged particles
hitting an antenna ever cause static discharge problems. If
it has ever occurred even once in history of this planet,
your assertions are wrong. It occurred in my antenna system
multiple times while I was living in the Arizona desert. There
was not a cloud in the entire state at some of those times.

According to the web source I posted yesterday, arcing can
completely eliminate corona because the arcing occurs *before*
the corona can possibly occur. The example given was between
two spherical electrodes. The corona example involved a
pointed electrode which caused corona to occur before the
arc.

> I think that idea comes from reading and believing wive's tales and
> rumors, and not thinking and experimenting for oneself.

I think you should stop worshiping the Corona God, go
out to Queen Creek, AZ and perform your experiments.
Please prove that every dust particle carries a charge
identical to the charge on every antenna.

You remind me of the host of scientists who believed that
the earth was never bombarded by meteors and comets
because they couldn't see more than a handful of impact
craters.

You can run the experiment for yourself, Tom. Set up an
inverted-V dipole and discharge a capacitor at one end
between one element and a ground plane. Guaranteed, you
will hear the noise in an RF receiver when there's no
sign of corona anywhere.

Cecil,

More fractured physics.

If every interaction between objects requires that somehow the charge is transferred to keep things "identical", how did those nasty dust particles get charged in the first place?

I am not arguing about antenna noise. I am questioning your misuse of physics. There are no charge equalization laws.

> question, however.
>
> How do you determine when the ionization threshold has been reached?

Corona invariably causes a glow at night. I have witnessed
such a glow but not very often. I came across a calculation
of the ionization threshold in volts yesterday while on the
web. I don't remember the exact figure but it was in the
thousands of volts for average air conditions and varied
with the geometry of the conductor.

But the point is that, by definition, it is not corona until
ionization occurs. A wire in the air during high wind conditions
can accumulate charge from the charged particles but until it
accumulates enough charge to cause ionization of the air, it
is NOT corona, by definition.

W8JI is confusing cause and effect. The transfer of charge
from wind-driven charged particles can cause localized corona
but that's just an effect, NOT a cause. And if the antenna
wire is not allowed to reach the air ionization level,
charge may accumulate but corona will not occur.

Under thunderclouds, corona often occurs. I wouldn't try
to speculate whether rain or snow noise is caused by
charged particles or corona. But I will certainly speculate
that in a state without a cloud in the sky, a charge can
be deposited on an antenna by charged particles.

How many systems have you looked at Cecil where you were right next to
the antenna while this was going on?

More than I have or many times less?

My bet is many times less. Probably none.

I'd bet you never were on a 300 foot or taller tower or on the roof of
a building, and I'd also bet you never had multiple antennas of various
tyoes to compare.

I'd wager all your data comes from what you picture in your mind.

Cecil,

First things first.

Ionization threshold has nothing to do with "voltage". It has everything
to do with field strength. This topic has been studied extensively for
centuries. Don't believe everything you find on the web, especially if
it requires "glow-in-the-dark" or "thousands of volts" as a determinant
for ionization.

Charged dust particles can *cause* corona but they
don't necessarily cause corona. If the air is not
ionized, corona is impossible.

I don't know exactly how many. All it takes to prove
you wrong is a single one. If you simply admit that
at one time in the history of man, a charge accumulated
on an antenna without the presence of corona, I will
be satisfied. When you assert that 100% of all charged
up antennas is caused by corona, it doesn't matter
if you are right 99.99% of the time. Logically, you
are 100% wrong if 0.01% of charged up antennas do not
involve corona.

When there is not a cloud over the entire state of
Arizona, charged up antennas in the dry, dusty,
windy Arizona desert are not caused by corona.

> More than I have or many times less?

I multiply 6 times 7 once and get 42.
You multiply 6 times 7 ten times and get 56. Do
you really think you are right? The laws of physics
are not supposed to be the results of how many
flawed experiments are run.

Charged particles can exist in the absence of corona.
Like the cave men did, rub some amber against some
wool and then touch it to your dipole. That pop
you hear is NOT corona.

When a charged particle touches a reference bare
antenna wire, it transfers part of its charge to
the antenna. You have already agreed with that.
The rest is simple physics.

Exactly how do you prove that all charged up antennas
are causing ionization? What instrument did you use
to measure all that ionization?

Cecil, if you're too chicken to do the experiment, just say so,
I'll understand. Also, quit misrepresenting my ideas. That's an
old Oakie debating trick that won't fly on this newsgroup. The first
thing you have to prove is that a charged particle striking your antenna
makes an audible noise in your receiver. Just because a charged particle
strikes your antenna doesn't mean you can hear it. I have an idea.
Borrow a big, old, awkward Texas kid from one of your neighbors.
Wash his head and blow dry his hair to get all the moisture out.
Now, have him stand out at your vertical and run a comb through
his hair. After the comb is charged, have him touch it to the antenna
while you listen to your radio inside the shack. See if you can hear
an audible click whenever the comb discharges into the antenna. If you
can hear something, it at least means that charged particles can make
a noise. If you can't,you have to rethink your position.
I know you go all gun shy and hysterical whenever someone mentions you
do an experiment, but it wouldn't kill you to try _something_ in order
to prove your point. You might learn something, too.

Of course, static field strength implies energy which is
proportional to volts squared. Here's a quote from:

http://www.ce-mag.com/archive/1999/novdec/mrstatic.html

"A corona discharge is also called a silent discharge. It
may be maintained as long as the breakdown *field strength*
is exceeded in some regionï¿½that is, as long as the *voltage*
of the electrode or the *charge density* of the charged
insulator is high enough."

Just before the field strength is high enough to cause
ionization, the voltage between the electrodes can be
measured. I don't see how ionization could occur at
zero volts which you seem to imply is a possibility.

4100. Re: fs: Kenwood kpt50 repeater radio programmer

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-16 15:22:27 UTC
From: Skipp is back <skippsayshello@yahoo.com>
Message-ID: <e6uibjkur1@skeeter.ucdavis.edu>
Source record: 57892
Cross-posted to: rec.radio.amateur.equipment,rec.radio.swap,rec.radio.amateur.antenna

Man, the below is an old post... anyway the used kpt-50 programmer
is long gone/sold. I bought up a number of the last units Kenwood
had at the time and have been slowly selling them off. The Epcom
price for the kpt-50 is about $330 at last glance, I was selling
them for about $245 list and applying various discounts to get the
end price just about or just under $200... say about $195 per
unit. The mentioned price is for a new (not used) programmer with
the matching (and really handy) kpg software for use with a PC. Using
the matching software with a pc is really the only way to go. You
can save and retrive both base station and repeater station files,
which include the frequencies and ctcss (PL) - dcs (DPL) codes to
your computer hard drive (archived).

Anyway, I'm still around and still a full line Kenwood Dealer. Please
feel free to email me if you have any questions. Find me using the web
page url just below.

cheers,
skipp

Hmmm.

10uF capacitor charged to 12 volts = dust particle

How much charge can a dust particle hold as it moves through the air Cecil? Does it eventually assume the potential of the air? Can I substitute a dust particle for a 1pF capacitor? For a 10pF capacitor? For ten farads?

Why would anyone tgink that proves anything?

On the other hand I've been a few feet away from antennas in an undisturbed environment, and I've seen and heard the corna many times.

BZZZZT! More fractured physics.

Here's a hint. Voltage is often poorly defined since it requires a
reference. Very few physical phenomena depend on voltage as a primary
parameter.

> I don't see how ionization could occur at
> zero volts which you seem to imply is a possibility.

Huh?? Did I say that?

> 10uF capacitor charged to 12 volts = dust particle

Nope, 1uF cap charged to 12 volts = charge.

One charged dust particle = charge.

I've never said I have ever heard a single particle
discharge. It was someone else who said that. I agree
with the 2000 ARRL Handbook when they said it was
"almost continuous". I have certainly heard that
"hash-type noise" get worse with wind speed. I wish
I had made S-meter measurements.

"Precipitation static is an almost continuous hash-type noise
that often accompanies various kinds of precipitation, including
snowfall. Precipitation static is caused by rain drops, snowflakes
or even *wind-blown dust*, transferring a small electrical charge
on contact with an antenna."

But what I am saying certainly makes a lot more sense
than your implication that all particles have exactly
the same charge as all antennas.

Yes, and the web page reference provided a well defined
reference between two electrodes with known capacitance.
There is *always* a relationship between electric field
strength and voltage. I disagree that they are unrelated
as you implied.

>> I don't see how ionization could occur at
>> zero volts which you seem to imply is a possibility.
>
> Huh?? Did I say that?

No, but you implied it when you said "ionization threshold
has *nothing* to do with voltage". Nothing is zero so you
implied an ionization threshold is completely unrelated and
independent of volts. Do you want to amend that statement?
Maybe: "The relationship between field strength and voltage
is sometimes difficult to determine."?

micro-amp,
> moving coil meter.
>
==========

The VLF capacitance to ground of the 30-feet high antenna is about
250 pico-farads. Total capacitance including the air-spaced tuning
capacitor = 550 pico-farads.

Assuming a capacitor breakdown voltage of 2000 volts and a breakdown
rate of once per second, then leakage over several antenna insulators
must have been about 1800 megohms. A not unreasonable figure.

It's surprising what can be deduced from a simple but fundamental
relationship such as -

Q = C * V = I * T

where Q = capacitor charge in Coulombs, C = Farads, V = volts, I =
amps, T = seconds.

It's only arithmetic. ;o)

You could now estimate the receiver noise level in dBm, due to
precipitation of rain drops of given average diameter, on an antenna
at a rate of N drops per second, each drop charged up to a potential
of V volts relative to ground. You would, of course, have to take
receiver bandwidth and a lot of other things into account. So it's
probably not worth the time and trouble.

Reg.

4108. Force 12 C-3 on 6 Mtrs

Source record: 57900

I have been told that the Force 12 C-3SS does not have much of a pattern on 6 meters. Today, however, on 6 meters, with a C-3SS, it appeared that I had good forward lobe, and maybe even some front to back.

Has anyone modeled this antenna for 6 meter. If so I would love to see the pattern.

Win, w0lz

Most raindrops don't have a little plate and a wire to ground.
In order to mimic a raindrop, Cecil, you'd have to leave the
ground terminal of your capacitor floating. Do that and tell me
what you hear. Anyway, you're still not addressing the real
issue: can you tell whether or not it's raining solely by
listening to the static noise on your antenna?

Nevertheless, air is in a constant state of conduction. It may only be picoamps per square meter but it still exists and it's what causes the earth to be a lousy capacitor.

If I remember right, your "Dr. Static" thought that you can't
have a voltage without the presence of a conductor. You ought to
read what these guys write before you quote them.

OK, then I believe you are assuming the short section is exactly 1/4 wave?
That's what I was after. I'm not convinced this is the case, but it is a
complex arrangement...matching 50 to an end fed half-wave.

> bob
> k5qwg

Yea, there's another double back at the top if you connect it there. And it is easier at th etop with twin-lead. ... simply makes that upper half-wave a single parallel sonductor, instead of one with a floating conductor next to it. I wouldn't be surprised if you couldn't widen the bandwidth a bit by playing with the length of that floating wire. However, connecting it at either the top and/or botton seems to make a big improvement very easily. I'd have to think a bit as to why the floating wire reduces the bandwidth...or the converse if the wider bandth is simply a case of a "thicker" condustor simulated by the parallel wires.

Huh? It is you who says the dust particles carry exactly the
same charge as the antenna they are encountering. Otherwise,
there is current flow in the antenna system which you deny.

> I am not arguing about antenna noise. I am questioning your misuse of
> physics. There are no charge equalization laws.

Huh? Place a charge on a wire. Doesn't current flow in
both directions until the charge is equalized throughout
the conductor? Did my college professors lie to me?

No, but in Queen Creek, AZ, I could look outside and not see
a cloud in sight. I could look at the weather radar and
see there wasn't a cloud over the entire state of Arizona.
I probably could be convinced that static electricity
during rain or snow was corona if I had not experienced
the clear-sky charged-particle effect in Arizona. I suspect
that neither you nor W8JI has ever experienced the clear-sky
charged-particle effect and therefore deny its existence.
I know better from my own personal experience as do others.

Nevertheless, that is *NOT* corona.

You will be glad to hear that Madisonville, TX is
experiencing rather severe corona effects today.
The knife switches that I use to vary the length
of my transmission line are snap, cracklin', and
poppin'. In this high humidity region of Texas,
I am not sure that charged-particle static ever
occurs. However, I am absolutely sure that it
sometimes occurs in Queen Creek, AZ, where I
lived for 11 years.

Jim, I forgot to ask. Do you have a bare-wire dipole
with no DC connection between the elements? If so,
does the coax connector ever arc when you disconnect
it from your system?

The first time I encountered this phenomenon in Arizona,
my G5RV coax connector was arcing while connected to
my IC-745. I disconnected the coax from my transceiver
and tossed it on the floor. It woke me up arcing and
scorching my carpet. Shorting the coax conductors
cured the arcing problem.

It was a clear starry night with the wind blowing about
30 mph. I have a hard time diagnosing that as a corona
problem.

4124. Resonant stub measurement

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-16 20:42:48 UTC
From: Chuck Olson <chuckolson01@REMOVETHIScomcast.net>
Message-ID: <NPCdnemFTdwxig7ZnZ2dnUVZ_vydnZ2d@comcast.com>
Source record: 57916

I think I've found a way to measure the resonant frequency of a shorted stub for the purpose of determining the Velocity Factor of twinlead cable. Unfortunately it requires the use of an HP3577A Network Analyzer, but I latched on to a used one a few years ago on Ebay, so I can have all kinds of fun with it. But there's a question of how to interpret the results.

I use two small one turn Faraday-shielded loops that I made out of RG58 a while back to induce or detect signals in various circuitry. For the purpose of this measurement, I loosely couple two of them, one from the analyzer source and the other to its receiver, about 4" apart with the loops parallel and axially aligned. Then I introduce the stub midway into the space between the loops, oriented for a maximum effect and observe a small peak followed by a small dip in the received spectrum sweep. My question is, which is the true measurement of the resonance of the stub - - the peak or the dip or the zero-crossing between them, and why? Up to now, I've felt the dip is the correct feature to use, since at resonance the stub patently steals a little energy from the coupled fields, but that doesn't really say why it steals energy, or why the peak isn't just as valid an indicator.

Thanks for your help,

Chuck, W6PKP

Hi Tom,

To support your statement with more specific characteristics, from a
1972 copy of "Astronautics and Aeronautics:"

That capacitor can be described as roughly 3.54 F to the
atmosphere at an elevation of 50km;

charged with a world-wide continuous 630 MW flow;

with a potential difference (average) of 350 KV;

and current (average) of 1800 A.

Taking this current, from earth, on a basis of cmï¿½, the current is
then 90 aA about 1 pA/mï¿½ as you said the same article goes as high as
2.5 pA/mï¿½. The difference is I used an homogenous earth model, the
author uses a real model with oceans and land with seasonal
variations.

"...the equipotential planes remain remarkably
horizontal in spite of winds, thermals, drizzle,
and cloud cover."

"few persons realize that when a person stands
in an open field on a clear day, his head has a
potential approximately 300V more positive than his feet
and .... The gradient averages about 180 V/m over land
in the summertime."

"The gradient in the austauch or mixing layer varies more
than at high altitudes because thermal convection
in this region often lifts ions and particles from such
sources as pollution, dust, and fog, thus generating an electrical
convection current."

This "austauch" layer, by observation of accompanying charts, appears
to be the first mile (actually 7000 feet) in elevation where
conductivity is flat at 200 micro-esu;
the electric field starts at 180 - 200 V/m,
to then vary downward to 60 V/m;
and Charges/cmï¿½ goes from 0 to -2 in the first 2000 feet,
and rises to +18.

The "austauch" layer may, in fact, be this first 2000 feet where the
charge density is negative. This accounts for the heavier positive
ion drift downward compared to the lighter negative ion rise into the
atmosphere. Be that as it may, the description is suitable for
antennas and high places.

4126. Copper tubing capacitors

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-16 21:24:55 UTC
From: "n3ox.dan@gmail.com" <n3ox.dan@gmail.com>
Message-ID: <1150493095.604886.118330@p79g2000cwp.googlegroups.com>
Source record: 57917

I'm thinking about how I can make matching networks for the center of a 40 foot doublet for field day. I have a couple of those 20 footer fiberglass poles and a center mount and want to be able to match on 20m, 15m, and 10m for now, and there are lots of ways I could do this, ladderline to the base and a manual or auto tuner, autotuner at the feedpoint, etc, etc, but what I'd really like to do is have switchable fixed-tuned networks as my intent for this antenna is to be set up in the middle of a field in the clear at the same height all the time, and I want to have FAST bandswitching.

An autotuner really isn't in the cards financially, and needs power.

So, inductors are easy. I've got 500 feet of #10 copper wire.

I need capacitors. Preferably very very cheap ones, and I guess I need a number of values.

So it seems like 3/4" copper tubing (type L) slipped into 5/8" copper tubing with an air dielectric has a capacitance of 30pF per inch and a breakdown voltage of 1300V, ballpark in the *ideal* case.

Two questions: It seems like having a small gap in a cylindrical capacitor like this probably makes it act like more of a lumped-element capacitor than, say, a length of RG-58. I guess the latter is more like 30pF per FOOT, and so you need to use a much longer line in terms of a wavelength to get the desired capacitance. Sound right to you folks?

Second, I know the actual breakdown voltage of such an object is going to be much less than 30kV/cm*the gap width. Anyone using copper tubing caps like this (I saw a magloop "trombone" unit some years back like this) and what are the dimensions and actual breakdown voltages of real units?

I guess polishing the tubes, making the cut edges rounded and so forth will help some, but maintaining the gap will be tough. I can easily derate for concentricity errors, but what about the ends? What is a good overlap of the two sections? Is it better to have the tubes be exactly the same length, flush with each other, or maybe have one longer than the other one so that the ends of one are far away from the ends of the other, or is it likely no difference? I can always go to a bigger gap; 0.035in diametral difference is probably pushing it for 100W use but I haven't yet calculated likely voltages across these things, so here I'll take any general comments on making coaxial caps that stand high voltage. I'd probably prefer air dielectric to teflon heat-shrink or something, I don't know how available that is.

I got in some trouble in high school by bringing in some 600volt 8
microfarad oil caps and discharging them loudly against the metal desk

when (I thought) the teacher wasn't looking. I never did find out how long they would hold a charge, but they would load up to 500-600 volts and stay that way all day!

Cecil,

If your college professors actually said that, then yes, they lied.

Try looking in any basic physics text. I believe you will find discussion of electrostatic forces, equipotential surfaces, fields, and Gauss' law. It is doubtful that you will find any technical description of charge equalization.

Simply grabbing random techno-factoids and assembling them into some sort of support for your case does not really help.

(I said nothing about dust particles. I merely asked you how they got charged.)

It isn't the charge that is equal, it's the potential. If there were a potential difference between two places on a conductor, there would be a current and then the conditions wouldn't be static. David K. Cheng addresses this in his book _Field and Wave Electromagnetics_. I think it's Cecil's memory that lied to him rather than his professors.

Hi Richard,
that's pretty much the basis of my interpretation of
Tom Rauch's experience with precipitation static. Some authors
(Feynman for one)claim the earthly capacitor is constantly being
recharged from lightning storms in the tropics. I don't understand
dust storm electrodynamics, though, but since Saint Elmo's fire has
been seen in dust storms it may still have something to do with
the earth's electrical field added to whatever produces the
potentials within the dust storm.

It is an approximation to estimate the reactance of a given length by
multiplying the length by a capacitance per unit length figure. Error
becomes significant as the length increases, and the estimate is
probably not accurate enought for you purposes beyond about 15% - 20%
of a wavelength (electrically) and is grossly wrong over 25% of a
wavelength.

We have three classes now, Should we increase or decrease?

I'm thinking we can reduce the number to two license classes:

One class for VHF/UHF so those people can screw up the repeaters, and one with a little harder test that adds HF privileges, for those that want to screw things up world wide.

It has been my experience that most people that are sharing their antenna designs on a web site have very bad drawings of those antennas so bad that it is hard to determine how to build them. Well I would like to help change that. If anyone here is actively maintaining a web site with antenna designs and would like better drawings, please let me know. I will draw them in 3D and give you the 3D model to put on your web site along with screen shots and or PDF drawings of the 3D model. For web site visitors to view the 3D model they have to download and install the free viewer and download the model. The viewer does work as a plug in to IE but it's not very easy to use that way.

Right. So I figure if I don't need to ever exceed 10-15 inches of line to build a capacitative stub on HF, it's better than if I need to get out to many feet of line to get the same Xc.

So, here's a question. I've built a piece of such line since I posted.

The outer conductor is 15 inches long, 0.995 inch inner diameter. The inner conductor sticks out on both ends, 1.5 inches on one end, 8 inches on the other (I've not cut it yet). The outer diameter of the inner conductor is 0.875 inches. The dielectric is air, except for 1/2 inch at either end of the outer conductor where there are some little nylon rings to keep the inner conductor spaced.

Incidentally, Zo of this line should be 7.7 ohms or thereabouts. I expect the velocity factor is not so far from 1.

I attached it to an MFJ-259 via a small length (about 8 inches) of RG-58 coax cable with a connector on one end and stripped ends (only about an inch) on the other.

At low frequency (~2MHz) the analyzer shows a purely capacitative load, about 200pF. (some of which is from the RG-58, some from the pipe)

However, this object (pipes+coax) has a series resonance around 30MHz! (R=0,X=0).

This was not expected as the line is only 0.04 wavelengths long at this frequency.

If I calculate Xc from Xc=Zo/tan(length in degrees) at 2MHz (Zo=7.7ohm), I get Xc=482 ohms. C=165pF, not too far from measured, considering that the 8 inch RG-58 probably adds a few tens of pF.

If I calculate at 30MHz where I'm finding a resonance, I expect Xc=31 ohms and Xl (Zo*tan(length in degrees)) = 1.88 ohms, so it should still be strongly capacitative.

Where's my resonance coming from?

OK, so I've done another measurement in the interest of eliminating some variables.

1) I've cut the tubing so that the conductors so that they're the same length within 1 inch, one end is flush, there's an inch of the center conductor sticking out of the other end.

The shield is still 15 inches long.

2) I connected a 47 ohm resistor in series with the stub, so I should expect 47 ohms at resonance. The outer conductor of the stub is connected directly to the "ground" terminal on the MFJ-259B, the center conductor is connected via the 47 ohm resistor to the center conductor of the SO-239 with a banana plug.

The open stub is now resonant at about 52MHz. (47+j0) I calculate its physical length to be about 0.066 wavelength at this frequency.

3) If I connect the stub directly (short <1 inch wires) to the meter, and set it to measure capacitance, the low frequency (2MHz) test shows 166pF, exactly what I'd expect from this length of 7.7 ohm line.

The conclusions I could draw from this:

1) I'm dumb and missing something.
2) I'm using the meter wrong.
3) The velocity factor of the particular 7.7 ohm line I've built is only 26%

Hi Chris

I just finished designing an antenna that I'm in the process of trying to describe on a web site. The antenna isnt of much value to most HAMs. I made it for receiving weather satellites (NOAA). I have a buddy in Finland who is helping me display the concept on his web site so anyone with an interest in weather satellite images can build their own hemispheric coverage antenna.
My buddy in Finland puts everything I send him on the web. So, this site may be confusing. But, the general idea of what I'm trying to make clean and clear is at http://213.250.83.83/~jerry/index.html.

How do I get an idea of the cost?

Jerry

Thanks Richard and Tom D.

I was worried for a while mythology and the magic dust (not Cheech and Chong style, but Texas style) would overshadow what really goes on.

Richard Clark wrote:
> "few persons realize that when a person stands
> in an open field on a clear day, his head has a
> potential approximately 300V more positive than his feet
> and .... The gradient averages about 180 V/m over land
> in the summertime."

We have to be careful with that!

Actually the impedance of the field is very high. When a person stands in an open field he actually perturbs the electric field very close to him because his body resistance is very very low compared to the impedance of the electric field. His feet are not really 300V more negative than his head unless you would replace everything below his eyebrows and above his ankles with a very good insulator.

On calm windless days the electric field in the air around a structure like an antenna is easily bled off even through extremely high values of resistance, and when the wind picks up, especially when there are particles of some type, the electric field impedance is effectively reduced.

There are some people who believe in magic. Some people think a tall metal structure has a potential difference between ends that builds up in storms, eventually charging the top of the structure so much it arcs to the clouds above.

To cure that pure fantasy they put little spikey balls on the top of their tower, somehow thinking the leakage from that corona that Cecil knows doesn't exist bleeds off the charge and makes the clouds above and earth below the same potential.

It's very strange how those people all argue with each other and argue against themselves, but then that's what happens when too much magic dust hits an antenna.

There will be no front lobe. BTDT. There will be a lobe to the NW and NE if you define the desired main lobe as north. It may end up better or a lot worse depending on the "reflector", which isn't going to perform well as one.

The only way triple f yagis work well is if the elements are swept forward. That pushes the right and left lobes from the straight elements into the center.

That's a great idea Chris. Also, it would be helpful if you posted some of
the antennas from QST on a website. For the past few years, they typically
do not have a clean electrical diagram of antennas described in articles.
They include so many mechanical details with the electrical, that it is
often hard to recognize something as simple as a loaded vertical. For
example, I never had the patience to figure out that GPS antenna they posted
a couple of years ago.

I don't really care what the antennas are for as long as it is a community share type project and not something you are only going to sell plans for. As long as I don't get to many requests, I'll draw it up for free. In return I'm hoping some of you guys out there who know antenna design can help me with some antenna designs. Right now I am trying to figure out a good design for a LEO Satellite Phone that has a frequency range of 1616-1626.5Mhz.

So if you can get email me some sketches or what ever you have I will try and draw it up. The email I use for news groups is bogus. You can email me at a real address by looking for the "email support" link on my web site linked below.

Hi Chris

I had tried to contact you before replying to the group by clicking on
"reply to sender". Now I'll contact you at your site.
I have absolutely *no* interest in selling anything associated with this
antenna. Heck, I've paid to get others to try it just to get confirmation
of its usability.

Thanks
Jerry

Please stop fibbing about what I said. As far as I know,
virtually all the localized static problems I have here
in East Texas is corona. I am not aware of any charged
particle problems in my high humidity environment.

But I experienced something different in the Arizona
desert that cannot be explained by corona.

Hi Chris

The antenna I want to describe was designed for LEO polar orbiting NOAA satellites. It works well at 137 MHz. It is sensitive to RHCP thruout the hemisphere, so I suppose it would be an excellant design for 1.6 GHz LEO satellites. But, with 3 inch dipoles, it would be relatively difficult to construct.
I dont have any test equipment for anything over 400 MHz. If I could do any measurements at 1.6 GHz, I'd try to build a prototype 1.6 MHz version of this "Double Cross" antenna.

For something that doesn't get much ink in the textbooks, static electricity can be an awfully important subject. I spent years trying every half-baked, nuthouse remedy I could get my hands on to try to get paper through a printing press without having sheets cling to each other due to static attraction. Nothing actually worked very well. There were plenty of people willing to sell me remedies, though. I'm surprised no one is marketing a corona killer for antennas.

That's too bad, since I've described that technique on this group a number of times in various contexts. It allows you to make a very nice 40/15 meter antenna, for example. Bending the wires of a 40 meter dipole in 30 degrees aligns the lobes on 15 meters, but doesn't alter the 40 meter pattern much. And of course it's widely used for TV antennas, where the upper VHF bands are about three times the frequency of the lower ones.

This doesn't make an extended double zepp as posted earlier. An EDZ is 5/4 wavelength, which has a single lobe in each direction broadside to the antenna when the antenna is straight. A dipole operated at three times its lowest resonant frequency is about 3/2 wavelength, and has four lobes in a cloverleaf pattern, rather than two in opposite directions like an EDZ. So it requires bending if you want just two major lobes in opposite directions.

Hi Tom,

Quite true. Its as if a needle has penetrated the equipotential
shells over that 300V span. Streamlines would probably reveal a dead
short to what are in the distance 300V/90aA = 3,333,333 GOhm resistive
paths.

The author's intent was to design a plane's auto leveling (in flight)
mechanism by sensing the voltage differential while banking. He
accomplished this by placing sensors at each wing tip turning the span
into a bridge circuit. He wasn't sensing voltage, but instead using
current. The plane would be already shorting out the potential, so he
had to turn this lemon into lemonade.

The problem was that the sensors had to grab hold of the current
before the massive short hogged it. The solution was to use mildly
radioactive isotopes to "make good electrical contact with samples of
air at two different points in the vertical potential gradient...."
Those radioactive sources were 500 ï¿½Curie Polonium Alpha emitters -
the kind I used to remove static from records back in the early 70s
(your solution to taking care of paper static, Tom D.).

If I cause 10 coulombs of charge to be on a 10 meter long wire, do I not have a uniform charge distribution of 1 coulomb per meter on the wire, under dc steady state conditions? Isn't this required for any equipotential surface?

I should have known you would have stated it already. My bad. ;)

There is also an interesting 2 meter antenna for sale on the net that
uses that method. 3 3/2 wavelength elements made as a sort of yagi as I
remember. I have no idea how well it really works.

Seems like you want something that once it is adjusted to the right capacitance it will probably never have to be tweaked again. I would go with brass plates. You can make up a nice little "brick" and then tweak it by grinding parts of it off or drilling holes in it. Sounds a little crude but really worked quite nicely for an antenna I built a long time ago. It did prove a little impractical though, Capacitance really seemed to change a bit with humidity. I never really solved this problem or even tried because I came by one of the old Heathkit antenna tuners that was a motor driven cap that you put in seies with a long wire antenna. Placing the brick in plastic box would have probably been a viable fix. Also consider that your linear caps may have quite a bit of inductance, just something else to figure into it all.

....and when we picture this stuff correctly everything works. For an example the cubical quad antenna.

Quads almost always have long insulated spreaders with long leakage paths that allow directors and the reflector to "float". So, unlike the typical Yagi, the elements can charge to whatever potential is around them.

Everything around the floating element is around the same potential as the element. There is no corona.

The driven element has a path to ground, as most antennas do, so it is at a different potential than stuff around the element. Unlike a Yagi, the quad has the advantage of not having very sharp multiple extended protrusions into the space around its only "grounded" element.

Not only does the only quad element with a connection that keeps it at earth potential lack extended protrusions, it also does not have the highest impedance point of the element at the point where corona or leakage current is likely to form. This means the quad, unlike the Yagi, does not have a very high impedance point of the antenna protruding into space around the antenna where any very tiny leakage discharges with very low current and very high voltage are better matched to the antenna.

When we don't get all hung up on the very obvious nonsense that a closed loop is somhow magically quieter than an open element by virtue of "dc short", or fixated on an odd idea that the particles hitting the conductor are the actual instant of noise generation, everything fits.

In conditions where there is corona or the potential for corona, quads are less susceptable to noise. As a matter of fact the very reason quads were used in their initial applications was in the moist high altitude environment of HCJB, and the quad element was used to prevent errosion of the dipole elements by corona into the moist air!

When we look at this, it is almost laughable the very people claiming corona can't be the root cause of what is commonly called p-static noise are often arguing quad or quad like antenna short the noise of particles striking the antenna to ground, and thus can't have corona.

Or worse yet they argue moisture prevents corona, when the entire reason the quad was "invented" was to prevent coronal errosion of dipole elements in the moist air at HCJB.

Dave,

No. A good conductor in DC conditions will have an equipotential surface. Charge distribution depends on the shape of the object and the external environment. The wire you describe will have higher charge density near its ends.

Electrostatic analysis would be a lot easier if what you suggested was true.

Jimmie, I like the idea of drilling some holes to tweak the
capacitance. Good idea for a set-and-forget.... nice.

I've also used PC board caps. I don't know what the Q of those is
like; I guess it depends heavily on the dielectric... I'm sure the
duroid microwave board is much better than regular G10 or whatever.
Never really used them with power though.

There was a good tip in QST last? month about using big teflon heat
shrink tubing to make caps that were inherent parts of vertical
antennas, but I checked some prices of teflon heat shrink in large
sizes and it's not cheap.

My previous comments about the charge on each particle of given
diameter which impinges on a grounded antenna wire appears to have put
you on the right track.

But you are now over-complicating matters. KISS.

A succession of random dis-charges constitutes a noise current induced
in an antenna wire.

Now carry on from there. You'll eventually sort it out.

Reg.

Hi Raymond,

Sounds like a good rationale, but you don't show a solution, just a
feel good answer. After all, you once assigned W = 0 and if that be
dimensionless or not, the product is likewise 0. You don't mention
what W = ?

As for a tube having transconductance. Yes, of course - if it is
conducting at all, and a stone cold tube does not conduct (aside from
parasitics which do not have transconductance).

To say
>of course (1/Cw) are ohms
does not satisfy your initial problem:
>> the final result for the fractionated gain has unit of ohm square.
which already acknowledged ohms to the point of too many of them!

No, your solution is found in the topology of the circuit, and the missing mesh. I see three of them, Bode saw three of them, you fellows decide to stop at two to the confusion of results. Simply put, your statements above do not describe equation 5-20.

When you guys hand in your papers at end of term, perhaps the professor will offer the solution.

Quads are also less susceptible to noise from charged particles
because they tend to distribute the charge locally instead of
through the transmission line like a dipole does.

Corona is like being pregnant. It either exists or it doesn't.
Corona is steady-state ionization of the air. Arcing can occur
without corona.

> Or worse yet they argue moisture prevents corona, when the entire
> reason the quad was "invented" was to prevent coronal errosion of
> dipole elements in the moist air at HCJB.

Apples and oranges, Tom. Since nobody has argued that high
humidity prevents corona during transmitting, your statement
is just an unfair obfuscation of the facts. On a clear-sky,
high-humidity day, the high humidity prevents corona on *receiving*
antennas. The antenna at HCJB did *NOT* report any corona problems
during receive.

The antenna at HCJB had corona problems when 10 KW of
power was being supplied by the transmitter. The energy
necessary to cause the corona was coming from the
transmitter, not from the atmosphere.

You apparently misunderstood what I was saying. I didn't say
the charge on the charged particle and the wire equalized. I
said, after the charge is transferred to a point on the wire
by the particle, the charge on the wire equalizes up and down
the wire.

But I am always ready to learn something new. Given two identical
conductive spheres with unequal charges, please explain the physics
that prohibits those spheres from equalizing their charges
when they are brought into physical contact.

I didn't say what I wanted to say in my last reply to this
posting so I canceled my first reply and am substituting
this one for it. It the older reply made it off my server,
please ignore it.

You obviously misunderstood what I said. I didn't say the charge
equalized between the charged particle and the wire. What I said
is after the charge is deposited on the wire and the particle
that did the depositing of the charge is long gone, the charge
deposited by that particle will equalize between two identical
dipole elements that are link coupled.

Let's say we have a perfectly symmetrical link-coupled dipole
and we deposit one coulomb on one element. Please explain the
laws of physics that prohibit those two dipole elements from
equalizing at the same charge.

Ok, I have a question for an antenna expert. I'm a UCF student designing a UHF RFID system for a new kind of robot positioning system, and I have two choices to make:

1. Circular vs. Linear polarized antenna for the RFID reader
2. Halfwave dipole vs. Fullwave loop antenna for the tags

The reader antenna transmits a signal that electrically couples the tag antenna, inducing a current that the tag uses to transmit its ID number back to the reader. It's a long range application, so it's important that I maximize the power transfer to the tag. Here's my current understanding of the matter, let me know if I'm wrong:

A L-pol reader antenna with a dipole tag antenna will get great power transfer, but there will be lots of null zones if the tag is oriented improperly.

A C-pol reader antenna with a dipole tag antenna will get great orientation indifference, but power transfer to the tag will suffer.

A L-pol reader antenna with a loop tag antenna will also get great orientation indifference, but sub-optimal power transfer.

A C-pol reader antenna with a loop tag antenna will get both great orientation indifference and maximum power transfer.

So I believe I want to do the last one, but I wanted to get some input from people with antenna experience, in case I have no idea what I'm doing, which is entirely plausible.
Thanks!
Nathaniel

Hi Nathaniel,

Both Loops and Dipoles are dipoles. This is not about geometry so
much as it is about phase driving two separate, but close antennas.

I doubt it any RFID tags are polarized, but I could be wrong. If so,
then you will need a more complex antenna for the reader. Either way,
you should check with the vendor of the tags. They have every
motivation to make sure you know antenna requirements.

The KMA log antennas seem more durable than Create or Tennadyne but not
sure about 80mph wind + ice. They can make you one from thicker
materials that would probably survive.

Dear Howard W3CQH:

A 26:1 frequency range is difficult to do well. Might you intend 500 MHz to 1300 MHz? A 2.6:1 LPDA is reasonably straight forward with design information in the ARRL Antenna Handbook (including mechanical information).

Use care when specifying survival of an antenna in terms of MPH. It is the equivalent Newtons per square meter (pounds-force per square foot) that is important. Several ways of describing wind speed exist and are not equal in terms of what they do to an antenna structure. Ask for pressure information.

I do not recognize the "30 Lb of ICE" specification. Most often, ice loading is specified in terms of size such as 12 mm of ice all of the way around each element (12 mm of radial ice).

It will help to know the task to be performed by the antenna. Tell us more.

Regards, Mac N8TT

Hi Nathaniel,

Just build two dipole antennas and try one first. One may do the
trick. The circular polarized (or more likely cross-polarized)
antennas are mostly to anticipate a random orientation of the tag. If
you can put all the tags in the same orientation, you only need one
(the favored) polarization. Figuring out which is relatively trivial.
If you need circular/cross polarized, it isn't much more getting there
than cabling.

Presumably by "join 2 lengths" you mean to connect two lengths in
parallel.

If the loss factor L is the loss in one length of the cable, won't the
loss in two parallel lengths be Plost=Pin/2*L+Pin/2*L, so Plost/Pin=L?

Hi Owen,

Hmm, each time I look at these equations, something is missing, but I
don't know what (probably because it is missing).

Simply put, two lines in parallel lose as much power as one line.
Nothing to be gained in that regard.

Given the looseness of use of the unit lb to specify mass and
(incorrectly) force, it is a bit ambiguous... but he probably means
mass. 30lbf of windage from ice loading isn't much on an antenna of
that type!

(We sin in the metric system as well! If someone asks me what I weigh
(being a force) I will answer in Kg (being a mass) instead of N
(force).)

Having said that, the impact of ice on the wind forces is probably
much more significant than the gravitational force due to the mass of
the ice.

Mac, I agree, radial ice loading is a more relevant specification.

4201. Sky noise temperature - 2m, 70cm, 23cm

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-18 08:10:49 UTC
From: Owen Duffy <owen@no.where>
Message-ID: <2q1a92pkre7o2kc0cechlks7pmh7rlacdn@4ax.com>
Source record: 57693

Googling about turns up a little, and only a little information on the expected sky noise temperature on 2m, 70cm, 23cm.

The information isn't very consistent. For example, articles that talk about the sky noise below 200MHz being 100K or more, and amateur articles talking about sky noise at 144MHz being "hundreds of degrees".

Similary, for 70cm a broad brush figure of 45K seems to be used, and others talk about 20K away from the galactic plane and 60K on the galactic plane. (Yes, they will be blurred together with a low gain antenna.)

Some discussions treat the "sky noise temperature" as if it includes spillover noise (eg in cold sky / hot earth measurements).

Can anyone recommend a reliable source of sky noise characteristics for these bands.

Additionally, I am interested in the range of ambient noise levels experienced for these bands for traditional DX activity (ie antennas at zero elevation.

Alternatively, are satellite beacons a reliable source for measuring station receive performance?

Or... is there some other better way of measuring station receive performance?

lbs is always force as far as i know. slugs is mass.

so long as we are confined to the planet earth, there is no difference
really. 1 kg (mass) always weighs 2.2 lbs (force). obviously if you go to
the moon ...

kilogram, slug -- mass
newton, pound -- force

Gravity

Hi Owen,

I seem to recall around 30K-40K for cold sky.

At 432 and above, everyone I know is using sun noise to evaluate system
performance. Have a look at K5SO's site:
http://www.k5so.com/Sun_noise.html

Most of us on 1296 EME use a GR1236 IF meter for sun measurements. Easily
resolves 0.1dB.

73,

Dale W4OP

Several of the EME software programs, such as TRACKER for MS machines, or Palmtrack for Palm OS, will give the noise temperature at several frequencies. Google for "EME tracking scheduling".

You could also get help from one of the 2 EME nets on 20m. They run from approximately 1000 through 1230 Eastern time on 14345. If you can't check in, you can listen to the net on the first link at http://taring.org using WMP or any other mp3 streamer, and you can email your question to Joe, K1RQG_ _@_ _aol.com (remove the clutter to use) and he will likely get the net to respond with lots of information for you. Checking there would get you the best answers on sky noise.

Alternatively, the sun is easy to find, and the numbers are published daily for at least 2 frequencies. The problem is extrapolating those numbers to as low as 2 meters. Discussions recently say the best known, most used, equation probably is not correct, even at 1296, and will be even less accurate at 432, let alone 2 meters. There was a corrected one suggested, but I would take any of them as untrustworthy at this time. Again, the EME net may be of help, as many net participants take regular, even daily, sun noise measurements at 1296. They can also give you tips on avoiding errors and calibrating.

Hang on, I didn't say "couldn't", I said I doubted it, and I also said I was asking a question. And you and others have given lots of information since, thank you.

I not convinced that corona is what I'm hearing, but I'm no longer convinced it's not, either.

That's good. You shouldn't be convinced. Especially if it is something just accepted and circulated without experimental results confirming it.

There are a lot of odd ideas that are deeply rooted, especially when it comes to electric fields, noise, and charges.

Look at the shielded loop thread that just went on! Someone started a whole thread just to show the shield blocked electric fields and "noise", when all the shield really does is help balance the antenna and eleimnate common mode responses.

The "dc path eliminates noise" and the "noise comes from each particle hitting the antenna and a dc path reduces it" are nearly as far fetched.

The potential difference is between the earth and space above the earth. Clouds can also become "charged" and have a large potential difference to earth and anything connected to earth, especially in bad weather. That's why the world has lightning hits!

Anything connected to earth and sticking up and out in the air will have a huge potential difference between it and anything in the space around it at the same height or higher.

The sharper, higher, and more extended the conductive protrusions are the worse the problem is, and the best ground connection in the world won't reduce it (it can actually only make it worse). Rain or snow or dust won't make the problem less either. Neither will high humidity.

I spent a lot of time and money trying to fix what I thought was the problem (the particles making noise) until I learned the folklore was wrong.

It is perfectly obvious, at DC and low frequencies, the resistances of the two inner conductors are in parallel with each other. So with a fixed voltage at one end there will be a greater power dissipated in a load resistance at the receiving end.

Outer conductor resistance has a secondary effect.

By connecting two cables in parallel the resulting attenuation will be smaller. But as Cecil implies, for exact calculations, cable impedance, cable length, generator and load resistances, and SWR enter the argument.

In general, it is a complete waste of time, trouble and cost to connect coaxial cables in parallel merely to obtain a different Zo impedance.

If a reduction in line loss is the objective, then the most economic and effective procedure is to use thicker wires in the transmission line and let line impedance look after itself.

I already explained that to you, Tom. Perhaps you missed it.
In the following diagrams, CH is the charge transferred to
the antenna by a charged particle or any other means.

Given a non-folded dipole, any equalizing of the charge between
the two identical dipole elements must flow through the link
where the noise is picked up by the receiver.

```
-------CH------+ +---------------
| |
/ /
| |
Link to
receiver
```

Turning the non-folded dipole into a folded dipole provides
a *local DC path* between the two elements. Most of the
noise will follow that DC path between elements instead of
traveling down the transmission line, through the link, and
back up the transmission line. Hint: Ohm's law.

```
DC path between elements
+------------------------------+
+-------CH-----+ +--------------+
| |
/ /
| |
Link to
Receiver
```

You avoided replying to this last time. One wonders why.
Please explain why you think the charge on the folded dipole
would not take the DC path of least resistance.

Dear Owen:
As you, and others, have concluded from my descriptions, I too have mass and force in separate bins.
I continue to be amazed at the facility with which MEs use "pounds" to indicate just what they want it to indicate. Every time that I do a mechanical design (or check a mechanical design), I convert to SI units with a careful check accompanying the conversion of whether I have converted forces or masses. Once in SI, everything is easy.

I have had discussions with some of my fellow P.E.s of the ME persuasion about this: they contend that they always know when force and mass is involved. I remain unconvinced.

A mass centered system (SI) is more straight forward than a force centered system where an assumed gravitational field is used.

Here in the North, ice plus a moderate amount of wind is most often what kills antennas having cantilevered elements.

Thanks for your comments.

After years off the air, I'm ready to get back on. I want to keep it simple though. I picked up a 6m/2m/440 Yaesu VX-7 HT at Dayton and I plan to use it for both base and mobile. I want an antenna that covers these 3 bands that I can mount off the side of my 80 ft. tower. (Off the side, because there is no way I can climb to the top anymore!) I'm not concerned with the gain, I just want something better than the rubber duck. Any product and mounting recommendations?

Depends on the PVC you use. Some of it is pretty bad. Put a sample in a
microwave oven with a cup of water and turn it on for a couple of minutes.
If the plastic gets hot it is bad for antenna use.. Probably OK for supports
but I wouldnt use it to house an antenna element

Cardboard soaked in fiberglass resin makes an excellent coil form. It's
strong , waterproof and RF transparent. Even better it you put a little
glass on it.

> ZL2DG

Assuming the cables are matched in each case, loss is the same.

Think about it this way. You have half the power through each cable. This means whatever loss you have, each cable now has half the power loss. When they are summed back together, losses are now the same.

Say you had one cable with 100 watts, and power loss was 1 watt. Now you use two cables and 50 is 50 watts in each and loss is 1/2 watt. You sum them together and you get 1 watt loss, and now have 99 watts.

That's the matched case.

In the mismatched case in limited conditions, what Reg says will work. For example at VHF and lower frequencies most cables are dominated by conductor losses. At cable less than 1/4 wl long will have decreased loss when it has some SWR in a direction that decreases current. By paralleling two cables that are LESS than 1/4 wl long, as long as conductor resistance losses dominate, you can find situations where losses decrease if the mismatch is in a direction that decreases line current.

If the lines are long increased SWR always causes increased loss. You'd have to be careful to avoid making a change that causes each line to have increased loss from standing waves, because if that happened line loss would increase.

Since 93 ohm line has terrible loss, I'd avoid it. A good line would be a short length of parallel 75 ohm line, but then who needs a 37.5 ohm line? I did that once on a 160 vertical, but the .05dB power I saved wasn't the reason. The real reason was so the 35 ohm antenna feedpoint stayed where it was instead of being transformed by the line.

Because your basic idea is so seriously flawed I never took you
seriously.

Anyone understanding the basic system at all would understand if the
little charges made noise from transferring charge, that noise would be
at a radio frequency. Anyone looking at what you drew and understaning
what you drew would also understand in order to short the noise energy
at the radio frequency the path would also be required to short the
good signal.

If the noise is at a different frequency than the good signal, then the
receiver itself will sort it all out.

There really wasn't any good way to answer an idea so fatally flawed. I
ignored it thinking you would figure it out on your own later, or that
Yuri would help you get a different perspective on things.

Chuck-

Thanks for the link. I went from there to the FCC's web site and
downloaded Bulletin 65 and its supplements, including the guide for local
government.

I followed another link and found a BASIC program called rfsafety.bas at
http://www2.arrl.org/news/rfsafety/rfsafety.bas by Wayne Overbeck, N6NB.
(In the Ham Radio supplement (B) to Bulletin 65, I found a reference to
the program written by Prof. Wayne Overbeck.)

Except for the first line of the program, it runs in Chipmunk BASIC on the
Macintosh. It may also run in Microsoft QBASIC, but I didn't try it. I
went ahead and ran all combinations I use, both mobile and at home.
Apparently you can absorb a little too much RF by standing next to a
mobile, unless you consider the duty cycle!

Absolutely false! Good grief, Tom, don't you even understand
impedance transformation? The impedance changes along a
transmission line with reflections. The impedance at the receiver
is NOT the same impedance as exists at the antenna feedpoint.
Since my noise problems were with a G5RV used to receive on 40m,
let's take that as an example.

G5RV dipole---30 ft. 300 ohm matching section--x--coax to RCVR

Let's assume a 50 ohm impedance at point 'x' looking toward
the receiver. What is the impedance at the dipole feedpoint?
Are you capable of that calculation? The 300 ohm matching
section is known to be 1/2WL on 20m so it is 1/4WL on 40m. The
impedance seen at the dipole feedpoint looking back toward the
receiver is therefore ~1800 ohms. A 500 ohm RF choke across the
feedpoint will considerably decrease the RF noise at the receiver.

So, Tom, which way would the RF noise rather flow? Through a
500 ohm RF choke at the feedpoint or down the transmission
line that is exhibiting an impedance of 1800 ohms. I thought
you were kidding but you really are trying to refute Ohm's law.

And I am astounded that you would assert that an RF noise
pulse would rather flow into the 1800 ohms looking into
the feedline than to flow through the 500 ohm choke
located at the feedpoint. Or through the straight copper
wire of a folded dipole.

But, as I have said earlier, I'm willing to learn. Please
tell us all exactly how your proposed violation of Ohm's
law occurs in reality. Please see my other posting involving
a G5RV on 40m.

I don't want to spend time looking at your other ideas when your basic concept of noise and selective sorting of noise though misapplication of Ohm's law is so far off base.

Why don't you take a few days an think about what the noise our receiver's hear is, and how that noise could possibly interact differently than a desired signal!

Don't rush. Think about it a while. It'll come to you and you'll understand your mistake.

> By the way Cecil, I'm absolutely serious.

So am I, Tom. For the readers who haven't been keeping up with this thread, let me relate exactly what you are serious about.

I had a severe clear-sky charged-particle problem in the Arizona desert. My G5RV was arcing at my transceiver's coax connector about once per minute. I wouldn't have been able to hear any signals through the arcing noise.

40m is my favorite band. I installed a 100 uH choke across the feedpoint. It eliminated the arcing and resulted in readable signals on 40m. I don't know what the signal to noise ratio was but I could hear and work other hams during the charged particle wind storms so the S/N ratio obviously improved.

You asserted that such is impossible but it actually happened to me about 15 years ago in the Arizona desert. Anything that eliminates the charged particle arcing more than obviously improves the S/N ratio.

Here's a challenge for you, Tom. Set up an arc generator across your receiver terminals in parallel with your antenna. Measure the S/N ratio. Turn off the arc generator. If the S/N ratio doesn't improve, I will adopt your Corona God religion.

Here's a repeat from my other posting. Set up an arc generator
across your receiver's terminals in parallel with your antenna.
What is the S/N ratio while the arc generator is running? What
is the S/N ratio when you turn off the arc generator? For you
to assert that there is no change whether the antenna terminals
are arcing or not is downright pathological.

Cecil,

I am a bit confused by your description. The arcing was once per minute. Presumably the arc occurred over a very short time, much less than one second. What was happening during the other 59 seconds of each minute?

I have no doubt that an arc would interfere with reception. What about the remainder of the time?

I was taught (in imperial units) to differentiate mass (pound) and
force (pound-force). That learning stood me well when we changed to SI
(metric) part way through school.

Practice may be different in different places, but I suspect that it
is laxness on the part of practitioners who refer to force in units of
pounds.

I just had a look at Wikipedia (which isn't the oracle), here is their
summary:

"The pound is the name of a number of units of mass, all in the range
of 300 to 600 grams. Most commonly, it refers to the avoirdupois pound
(exactly 453.59237 g), divided into 16 avoirdupois ounces. There is
also a unit of force corresponding to the avoirdupois pound, see
pound-force."

Wikpedia highlights just another aspect of the unit, its flexibility!

Owen
PS: a slug is a unit of mass, and equivalent to about 14.6Kg or
32.2lbs. I don't think it is in wide use!

That tells you the loss when in an intense field at microwave frequencies. It doesn't tell you a thing about the loss near a typical HF or VHF antenna, except that if it passes the microwave test it's probably ok. Many materials which fail the oven test are fine for other applications.

PVC insulation on wire won't hurt an antenna noticeably, nor will PVC at low-electric field points like a dipole feedpoint. I'd avoid using it for an insulator at high field points like the end of a wire antenna or the base of an electrically short dipole.

The main problem PVC will probably cause is to detune(*) the antenna because of its dielectric constant. If you can adjust the element lengths to compensate, it probably won't be a problem.

(*) By detune I don't mean that it just changes the resonant frequency. It'll affect the pattern as well.

Hi Al

I am using 1/2 inside diameter PVC pipe (white stuff from Home Depot) to enclose three foot lengths of TV 300 ohm twin lead folded dipoles at 137 MHz. I have done the microwave oven test and couldnt detect any temperature increase. I measured the antenna's input impedance with and without the PVC cover. I detected very litle change when the PVC is included. The antenna seems to have the same sensitivity with and without the PVC.

I'd expect my experience to convince you that PVC is an OK covering for 2 meter dipoles. How much change do you see when you Grid Dip a dipole with and without the PVC??

Jerry

This is a reasonable starting place, but you're likely to find that a
multiband HT has a couple of limitations which make it less than ideal
for use in base and mobile applications.

For one: HTs tend to have broadly-tuned front ends, optimized for fairly
low incoming-signal levels. This is what's needed to provide
wide-range multiband operation with a rubber dummy-load antenna.
Unfortunately, as a result, many HTs are very prone to strong-signal
overload and intermod, especially when hooked to a good antenna. If
you hook an HT to a halfwave dipole or full-length quarterwave whip on
a good ground plane, you may find it being "blasted open" by pager
signals and other strong local transmissions. This can be a real
limitation for base-station operation, and sometimes requires the use
of a narrowband notch filter to reject the pager or other strong
out-of-band signals.

In mobile operations, the lack of a separate squelch control can be a
problem on some HTs. Desired-signal and interference levels can vary
quite a lot as you drive along, and it's no fun at all (and not very
safe) to have to try to hit an HT's buttons to bring up a
squelch-setting menu while driving.

An HT is usable in both base and mobile situations, but if you find
yourself using it a lot you may also find yourself wanting a rig with
a more robust front-end. A small mobile radio could serve that
purpose in both mobile and base applications.

Bearing in mind that most HTs suffer from IM (probably due to lack
front end selectivity), you might want to avoid wideband antennas such
as discones. Even on relatively narrow antennas, you may still
experience nuisance mute opening if you do not use CTCSS on monitored
channels.

>Should I switch to something else ?

Your brain, not his.

Some PVC is better than others, but I use it often. I use cpvc or the white pvc for antennas. The velocity factor is changed so the lengths are a bit shorter, but once trimmed, the antennas do well. I either use the PVC for insulators or for holding the wire rigid. I built many a dipole inside PVC for vertical or horizontal use. I also use it for insulators or spacers on open wire. Never had a problem with it.

Good luck

i hope this helps

Hi Tom,

I've been reading with interest this thread. Personally I think that you and Cecil are arguing past each other on this, but whatever people do for entertainment is cool with me.

On to what you have posted...

I'm a little confused here; are you saying that the discharge (whatever it may be) is restricted to only one frequency? I'll admit stupidity on this, but I always though that static discharges are inherently pretty wide band. Why would they be restricted to a single frequency? length of the discharge, and all it's influences?

> If the noise is at a different frequency than the good signal, then the

4249. Voltage vs. Current Balun - OCF Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-19 02:16:08 UTC
From: KC2PIH@gmail.com
Message-ID: <1150683368.339372.191010@p79g2000cwp.googlegroups.com>
Source record: 57741

I just installed a Off Center Fed dipole where one leg is 45 feet in
length and the other is 90 feet long. When I checked
the balun feedpoint (SO-239) with my DC ohm meter, there was a circuit.
The manufacter states its a 6:1 ratio balun and after my
test, I assume its a trifilar type. The antenna truly is "no tune" on
the 80/75, 40, 20, 17, 12 and 10 meter bands.
60, 10 and meters are all within the range of the internal tuner of my
radio.

But I was wondering what impact using a voltage balun (assuming I am
correct) has? What would be the effect of changing to a
current balun in this design? Does the OCF dipole require feeding with
balanced voltage as opposed to balanced current?
Also, I've read things about voltage baluns indicating they can't
handle a mismatch well - is that true?

Thanks,
Scott, WU2X

I'm reasonably happy with a 2m receiver that has a noise figure of 1.5db
or less. A good antenna system should be able to exceed the noise floor
of such a receiver, pointed just about anywhere in the sky. The galactic
plane should be enough

You are just showing your extreme ignorance, Tom. Many of
us have experienced exactly that problem. Jim Kelley reported
it just a couple of days ago caused by Santa Anna winds in CA.

Just because you have never experienced it is irrelevant.
To be consistent, you must also assert that Jesus never
existed because you never met him.

Another jab from Tom da scientwist.

I listened to someone's advice: "do not engage in the pissing contest with skunk"
I said what I know, you said what you know, anyone can verify by building and testing the shielded loops and judging who is full of it.

Shielded loops work as shielded loops, attenuating local noise or interference with source located within fractions of wavelength from the antennas, if you know or admit it, or not. It is a FACT that any half baked ham can observe and verify. You can mumbo - jumbo your theories and display your falacies on your web pages all you want.

You can call the shield to be an "antenna" or whatever you like.

I thank you for another subject for entertainment and for the "Mythbusters" articles, when time will permit me. Right now I am busy rejuvenating 175 acres of antennas and building mother of all contest stations. Barely time to have a pi$$.

Keep it up!

An OCF antenna is designed to be unbalanced. If you balance the
voltages, the currents will be unbalanced. If you balance the
currents, the voltages will be unbalanced. Unbalanced antennas
are unbalanced antennas. As Aristotle and Ayn Rand said: "A is A".

Ahm,
like there are no molecules of air being moved by the wind and rubbing on conductive parts?
When part is not grounded, it will not accumulate the charge?
If the charge exceeds dielectric strength of the insulator (connector), the discharge in form of spark would not happen?
Like ariplanes do not accumulate charge when flying? Or my 72 Buick?
Like Cecil is completely off the rocker making stuff up just to make himself look foolish? Hmmmmmm!
Too much funny stuff going on here from scientwific community. :-)

I would just like to publicly give a big thanks to Ed at KMA antennas
http://www.kmaantennas.com

I have received much appreciated responses to my questions on this and other RF related newsgroups but the ongoing support that Ed has provided me has "blown me away". It is difficult to find people these days who are so eager to go out of their way to provide help without expecting anything in return.

Based on this experience, I have no hesitation recommending KMA antennas for anyone who is looking for excellent products with even better customer support.

regards

David Huisman

O.k., Cecil, prove it experimentally. Many of you
may have experienced a problem, but you don't have the
foggiest notion of what caused it.
Making up causes in your head won't make them real. Making
up names, such as "clear-sky charged-particle problem" won't
magically prove them. Arguing incessantly doesn't
bring them into existence either. The only thing that makes
any sense, now that you've made a theory up in your head, is
to prove it with a series of experiments that anyone can
do to prove, or disprove, the fantasy. If you can't do that,
only fools will believe you.

Would you like to tell me how airplanes accumulate charge, Yuri? Would
you like to give me the results of the experiments you're always
threatening to do, but never get around to doing? Would you like
to explain the triboelectric effect and how it relates to antennas
and transmission lines? Perhaps you're an expert on atmospheric
electricity and can tell us all about it. I'd especially like to
hear how the wind "rubbing on conductive parts" causes noise. Cecil
was too chicken to do any meaningful experiments with this, maybe you
can inspire us with your courage and show us how it's done. It'll
sure beat the tired, old attempts at sarcasm you're always posting here,
and probably increase your credibility, too.

All I am doing is quoting the 2000 ARRL Handbook, Tom. I don't have to prove anything. It is up to you to prove the 2000 ARRL Handbook wrong. Here's what it said:

"Precipitation static is an almost continuous hash-type noise that often accompanies various kinds of precipitation, including snowfall. Precipitation static is caused by rain drops, snowflakes or even *wind-blown dust*, transferring a small electrical charge on contact with an antenna."

So please prove the ARRL wrong.

I don't have to do any experiments, Tom. The ARRL has already
done them for me. From the 2000 ARRL Handbook:

"Precipitation static is an almost continuous hash-type noise
that often accompanies various kinds of precipitation, including
snowfall. Precipitation static is caused by rain drops, snowflakes
or even *wind-blown dust*, transferring a small electrical charge
on contact with an antenna."

If you don't agree with the ARRL, please present some proof
that they are wrong.

> How about learning some experimental technique?

I would if it was necessary, Tom. But I am relying on
the 2000 ARRL Handbook just as I rely on it for many
facts:

"Precipitation static is an almost continuous hash-type noise
that often accompanies various kinds of precipitation, including
snowfall. Precipitation static is caused by rain drops, snowflakes
or even *wind-blown dust*, transferring a small electrical charge
on contact with an antenna."

The onus is upon you, Tom. Please prove the ARRL to have made
false statements.

Not quite. Testing on rules, regulations and technical knowledge is a bit different than testing on one specific mode of communication. I use CW, but considered the continued archaic CW testing requirement to be silly and outdated. It should have been dropped 30 years ago.

We give driving tests on the ability to drive the car and follow the regulations. We don't test on the proper operation of a buggy whip or care and feeding of horses. While people still enjoy riding horses and driving around in buggies, they do this of their own free will and no one is forcing it on them through a testing process to get a driver's license. The horse as a general means of transportation is over. We have evolved beyond that, but people still ride horses for fun and enjoyment and the government does have to force it on individuals just in case we ever have to go back to using horses for transportation in an extreme emergency.

this is true. if you are in the top 0.01%, there are other clubs which may be more suitable.

now W8JI does own several relatively expensive towers. IQ is often strongly correlated with financial success (at least below 130 to 140 IQ). so i guess i'm playing devil's advocate, but the guy can't be a complete idiot.

take care,

But it is "The Bible" of Amateur Radio and this is an Amateur
Radio newsgroup. Anyone disagreeing with the 2000 ARRL Handbook
should be able to quote some technical references to the contrary.
Where are the technical references that contradict the 2000 ARRL
Handbook statements on "precipitation static"?

You have 500' of wire -- why bother with any switching/matching networks?

Just cut dipoles for each band and feed them off of the same feedline.

If the current is unbalanced, this would mean current is likely to flow on the coax then? So perhaps the reason a voltage balun is used is to merely transform the impedance 6:1 and purposely allow the feedline to radiate? The maker of the antenna (Buckmaster) doesn't indicate any particular length of 50 ohm coax be used, but I saw a huge change in SWR and bandwidth on the upper bands when I lowered the antenna by 5 feet. Maybe this explains the behavior I saw.

I don't have time to engage in pissing contests.
There are some people here who "argue" that something is not so, because they have a theory that "it can't be".
Most of my arguments or descriptions are based on reality that I or others observed and can be duplicated. If you or anyone doesn't believe in them, you can duplicate them and see for yourself. I will gladly provide details.
I am not employed or reporting to this esteemed RRAA NG, so it is at the end of my list of priorities.
Some of the misconceptions are duly noted and in due time, when I have time to sit down and write it up, I will do so.
The point is, that if Cecil has seen sparks coming from his coax under clear AZ skies, or I have seen that small loop antenna shield DOES suppress local interference - measured, seen, experienced - than arguing by scientwists is just foolish, if not pathetic.
Who's "credibility" are we then talking about?
I do not proclaim to be a scientist who spent tax dollars investigating phenomena and formulating rock solid theories as why. I am more of real engineer, who when sees some erroneous stuff posted, and I know it to be otherwise, I say my piece.
Isn't it interesting that real engineers get hammered on tangents by scientwists who are wrong and are trying to justify their "truth" by some mumbo-jumbo and obfuscating the real subject? If that's what turns them on, than they can have a field day with it.

"It'll sure beat the tired, old attempts at sarcasm you're always posting here"

Yes, use thin walled glass fibre pipes!

PVC is not a coherent type/class of material. The producers use all kind of cheap crap as filler material or as pigment. The common rule is to use white PVC as most other coloured PVC contains graphite or oxide based pigments.
However, some white PVC's have chalk as a whitener and as a filler to make the PVC being formed better in the production gear. It's less sticky that way.

Some PVC materials are even "soldered" with 70MHz RF!

No, the Microwave oven test doesn't tell you the whole truth - just a hint.

I use very thin walled glassfibre pipes but with a foam filled inside. I use the expanding "gluey" insulation foam. When dried, the strength of the pipes have increased dramatically and they bend less in the wind.

Cheers

Dan / M0DFI

Two possibilities, if you think the PVC is detrimental.

1. Try hollow fiberglass blank arrows. (if the available length is long enough) They used to be available at certain sporting goods stores, or you could buy an arrow and cut the ends off. I made a super 2m quad with this technique. I just used a 1x1 wood boom with two snug fitting holes drilled at right angles, and slipped/centered the arrows used for spreaders.

2. Wrap the entire PVC in aluminum foil, and tape in place. From experience, I know this works at 10 and 15 meters when wrapped around bamboo poles.

5 WPM is easy. esp if you use Farnsworth.

i'm at 18 WPM, and i can copy contest exchanges at 30 WPM. i haven't made a
CW QSO in 10 years!

i think the code requirement should be 13 WPM plus for the upper classes.
keeps the riff raff out.

i've been considering an antenna for the audio frequency range plus 1 to 20 hz. basically a big coil would work.

i've thought about using a steel drum, but i don't have room for that in my new QTH. mu metal rods would be very expensive, even ferrite would be expensive for an 100,000 turn antenna.

not sure what to use. maybe steel core.

The short answer is because I like building antennas.

The more detailed answer is that I've got a forty foot long rotatable doublet made from some of those 20' crappie poles, and I want to match that. Making a fan dipole out of it would not really be possible. I'm already going to do that for 40/80 for FD, but the doublet will work well for the higher bands.

I'm eventually looking to have a 40-10m inclusive extremely lightweight rotatable antenna with good efficiency on an easily erected mast. On 40m/30m I already have a loading and matching coil to make it a "shorty 40" style shortened dipole. For 20 and up I don't need loading I just need to match it. It's going to be nice because it is tree independent. I could set it up in a parking lot on a light mast if I needed to.

Simple is not my style for field day. In a pinch I'll throw up simple dipoles. In a real emergency, I'm not going to go fancy, I'm going to go simple and resonant.

For field day, though, I like to put weird things up. I built a 3 element 15m yagi one year just for FD. The year before, I built an aluminum tubing trap dipole for 10/15m.

If 15 and 10 are dead as I expect they might be, I might even turn the crappie pole antenna into a delta loop for 20 only.

easy for you

not for me

I spent 5 years in my teens taking a test every couple of weeks towrds
the end. I did get so I might pass either the sending or receiving on a
given day but never both

guess from that data I suspect isf I had the time and schedule I could
mange to pass a receiving or better still a sending test in roughly a
year bt I don't my schedule leaves very busy eroids and very slow
eriods

but all this is beside the point
nothing in the treaty give the USA the requirement to make such a test
and nothing in the consitiotn reglates the matter so the power to use
hf specturm is resvresed byt eh 10th amend to the states or the people
themselves (para the constititon

unless the power to impose a code test can be shown to exist in other
section such preahps shwoing that it is "nessacary and proper" an
arguement that could have been made say when the miltary needed to warn
us of freqs they were suing in cw or some other argument, the FCC and
th congress lack the legeal power to maintain the test if challanged,
an expensive and unpleasent task

The Carolina Windom is designed to radiate from the vertical
section of the feedline. You could duplicate that function
by installing a husky choke a few feet above ground. The MFJ-
853 is an inexpensive current meter that allows one to
measure the current on the coax braid. Mine arrived today.
It needs a little modification to allow the core to open
without needing the strength of Sampson.

High permeability ferrite (manganese zinc) is fairly cheap in bead
form, and these can be glued or clamped together (with nylon
all-thread) to make arbitrarily long rod forms. For example, 5000u,
5/8th inch diameter, by 1 and 1/8th inch long beads (Steward part #
LFB159079-000) cost less than a dollar each from Digikey, in quantity
of 10. This will make an 11 inch long rod with very low loss at low
frequencys (less than 100 kHz). And the hole down the center eases
the problem of mounting the rod in a drill press to make the winding.
You just slip a chunk of 1/4" all-thread through the glued rod and
run a nut against each end.

Full text at:
http://buyit.philly.com/findit/search/results.jsp?catId=krd_philenqda...

This is a new on-line ad placed in Philadelphia Inquirer and Philadelphia Daily News on www.philly.com (see full text below) about the secret aerosols rooms in US. You can find it by searching "secret", say, in the ad section of philly.com.

Democracy can not function effectively without the informed public. As a former NASA Langley scientist working in the area of nanotechnology and nanoscale particles, I have been recently exposed to the establishment of secret gas-aerosol rooms inside of United States, at least in the Mid-Atlantic region (from Philadelphia to Virginia). First, the highly irritant aerosols have surfaced at the NASA Langley Research Center in several safety accidents. Investigations were blocked, probably, because of lack of Congressional approval for such financially-lucrative research at NASA. Later, these aerosols had been encountered outside of NASA in Virginia, Delaware and Pennsylvania. This points out to yet another proliferation of originally-sensitive technologies into domestic American life to hurt and harass people without a proper oversight and much control. This amounts to torture, extra-judicial prosecution and authoritarian intimidation tactics.

The use of such irritants and the operations of the secret gas-aerosol rooms are gross violations of human and constitutional rights of American citizens and various domestic and international laws.

----------Full text of an ad on philly.com----------
TORTURE IN USA: Secret Aerosols Rooms

US Scientist needs legal help dealing with the secret aerosols rooms (SARs) operated illegally in Philadelphia area, Newark (DE), Hampton and Williamsburg (VA). Highly volatile aerosols with and without bacterial content cause dry cough, airways and eyes irritation, chest pain and inflammation. FBI and Homeland Security associates are likely operators of SARs, while collaborators may be hotel staff and landlords, who get financial/material or other incentives. US citizens

and kids are victims.

Cecil -

I was starting to think that this antenna is acting like a Carolina Windom - and I was going to ask how to determine if there are common mode current on the coax (thanks for the tip on the MFJ) . Is the 22' length of the coax of the Windom critical or is that just a minimum length? Also, if the coax is burried right below the balun at ground level, does this at all act like a choke? Since I have a barrel connector there I could also ground it at the point - any point to that (besides lightning protection)? I guess if the choke is working then grounding at that point will have no effect.

-Scott

Dear Mr President:

The FCC has been dumbing down ham radio for several years now. This has hurt the integrity of the service and is bad for America. They are planning to dumb it down again really soon now and their plan will make ham radio like CB and it will be bad for America. We already have one CB service on HF, we don't need two. Please pressure the FCC to endorse the following items for the good of the service and America. I wish you could run again for a third term, I would vote for you. I'm glad Al Gore wasn't able to steal the election, and John Kerry would have been a disaster, he'd be kissing terrorist butts and brown nosing them. Thanks for the fine job you're doing protecting and leading America.

Hello,

That's true at UHF but it should be OK at least for the 2m band depending on
the PVC type.
The better choice is PTFE but it's not really cheap!
Another alternative is glass fiber (or wood).

psychiatry has been around hundreds of years and it's still considered
primitive by many. relativity has also been around 100 years, and it's
still pretty damn speculative.

and IQ is not intelligence. it has a 0.9 correlation with g factor as i
recall.

psychometrics have biases too. for instance, if the test uses the term
"quarter" as a unit of currency, the test is tied to the US and a few other
countries. a test that uses integer sequences like the Fibonacci is going
to be easier for a mathematician, who is trained to look for those patterns.
a test which uses analogies from 18th century English literature is not
going to be accessible to some people from Asia.

i could go on and on. some of my criticism is not leveled at
Stanford-Binet, but psychometrics in general.

also, i'd hope that whoever wrote the test is significantly smarter than me.
if not, what is the point? that dumb people can invent questions that i
can't answer?

the general rule is L = 234/F, where F is the frequency in megahertz, and L
is the length of a quarter wave element in feet.

this is a strange troll, can't you come up with something better?

I'm sure this very erudite letter, full of specific facts and the
results of many studies to prove it's point will immediately cause
the President to put aside all petty concerns (like the Middle East,
energy problems, changes in Medicare, investigations of members
of his party and staff, Iran's nuclear program, North Korea's ICBM
test, etc.) and order the FCC to get rid of all no code Hams.

> length?

I suspect it comes from the fact that 22 feet is very close
to 5/8WL on 28 MHz. If the vertical section were made any
longer, it might result in high angle radiation on 10m.
They probably also figure the antenna will be mounted at
least 25 feet in the air.

> Also, if the coax is burried right below the balun at ground
> level, does this at all act like a choke?

Burying probably dissipates common-mode power but if it's
dissipated, it's not radiated. Best to force that energy
into the antenna where it belongs.

As a matter of fact, I took both the American and English
IQ tests when I took the MENSA tests. My percentile rating
was twice as good on the American test with its dollars
and cents as it was on the English test with its pounds
and shillings. Obviously, those tests are biased. The
English language is a prerequisite, for instance.

You were taught wrong. If you use pounds in a formula that wants mass such as F=M*A you will get the wrong answer. So lets say you weigh 200 lbs on earth where A = 32 ft/sec^2. You can then calculate your mass by solving for M = F/A or 200/32 = 6.25.

When you are doing physical calculations it is very important to use the correct units, other wise you calculations are meaningless. Suppose you want to know what you will weigh on the moon where the acceleration due to gravity is 5.25 ft/sec^2. F = M*A if you use 200 for your mass you get, 200 * 5.25 = 1050, that indicates you would weigh 1050 lbs on the moon. Which is clearly wrong. Trying again with the correct units and you get, 6.25 * 5.25 = 32.8, now that sounds more like what you would weight on the moon.

In the non scientific world, where the metric unit KG is used for weight, M=F*A works just fine if you put what you call "weight" in KG in for M in the formula.

It's arguable which method is better, using mass or force units for weight. What you want to know is do you need to change your weight, if the doctor tells you that you need to loose weight, that's easy just move to the moon, done. What he really wants is for you to loose mass. So your weight (force) can change with gravity, but your mass doesn't change. Unless of course you loose weight ;)

Hi Chris,

Language is a strange thing. For instance the doctor would probably
prescribe a laxative if he wanted you to loose weight.

I don't know that answer either but I'm sure it is higher than that. I have seen coaxial relays with SMA connectors that can handle 400 watts at a higher frequency than 50 Mhz. Also get an N connector and a BNC connector and do a close comparison of the pin and the shield inside the connector. They look pretty close. In fact an N male will connect to a BNC female, just no way to hold them together. The other way around doesn't work because the BNC retention housing gets in the way.

F = MA
F = 1 pound * 32 feet/s^2
F = 32 pound*feet/s^2

you will note that pound(mass)* feet/s^2 is NOT the pound force unit. the
pound force unit is slug*feet/s^2. there is nothing wrong with the pound
mass unit per se.

you alluded to slugs.

F = MA
F = 1 slug * 32 feet/s^2
F = 32 slugs*feet/s^2 = 32 pounds

anyone else having flashbacks to particle dynamics class?

That's 6.25 pounds mass, I presume, for someone weighing 200 pounds force.

In my entire engineering school curriculum, I had only two courses which didn't use the metric system, Statics and Dynamics, taught by the civil engineering department. I have vague recollections of pounds force, pounds mass, slugs, and poundals. As often as not, my answers were off by g^2, since I never could remember which ones already had gravitational acceleration built in and which didn't. But I developed a method to deal with it. When presented with a problem, I first converted everything to SI units. Then I solved the problem and converted the answer back to U.S. units.

What a horrible system! My hat's off to the Canadians, who had the will to convert, and established -- and stuck with -- a systematic program to do it. What the U.S. did was to declare the metric system to be official ("Mission Accomplished!") and change whiskey bottles from fifths to 750 ml (which was promoted by the booze industry because it made the bottles just a little smaller and they could charge the same price). Wow.

i first heard of slugs at age 7, but i've never seen them used in an engineering class.

we used SI almost exclusively in university and high school. i was taught there that pounds is a unit of force (not mass). however Wikipedia claims pounds is a standardized unit of mass, not force.

so we are both right really.

as i've noted in another post, 1 slug at in Earth's gravitational field is ~ 32 pounds, so it's a convenient unit to use.

so basically if NIST (or whoever) defines it as mass, then we are stuck with it.

"honey do i look fat in this dress?"
"no baby, you are no more than 5 slugs or so."

No, it is 6.25 slugs of mass. There is no such thing as pounds of mass.
Sorry for leaving off the units in my last post. Just because
someone says x KG of force or x lbs of mass doesn't mean that KG can be
force and pounds can be mass.

Distance:
Meter, Feet
Force:
Newton, Pound
Mass:
KG, Slug
Time:
Second, Second (Can you imagine if there were different time units in
each system?)

All other units are derived from these. Actually Newtons and Pounds can
be derived from time, mass and distance. 1 newton = 1 KG*M/s^2 and 1
pound = 1 slug*ft/s^2. Which brings us right back to that fundamental
formula F = M*A, 200 lbs = 6.25 slugs * 32 ft/sec^2.

>bill k2wdgh

By chance I made one at the weekend. 113.5", 1/2 " diam ali tubing. I
used the yoke of an old TV CRT as a choke balun with a few turns of
UR67.

If you don't have space, a simple cubical quad is pretty compact.

Thanks to all that have answered my original post - but the information that I seek has not been answered.

I understand that section 207 of the FCC telecomm act 1996 contains information that I might be able to use to help me in this matter. Where can I obtain a copy of Section 207? I cannot find it posted on the FCC website!

Thanks,

please read Wikipedia. Owen is correct. pounds are firstly a unit of mass,
and secondly a unit of force. Wikipedia cites several sources.

200 pounds of mass weighs approximately 200 pounds of force on the surface
of Earth. 1 slug is 32 pounds of force on the Earth.

pounds-mass is standardized to kilograms, which are in turn standardized to
an alloy bar or other methods.

everyone who is arguing that pounds is not a unit of mass, please see:

https://carnot.physics.buffalo.edu/archives/2002/07_2002/msg00062.html

this post cites a NIST publication, which is definitive for the USA. there is no room for argument.

if you don't live in the USA, well a pound can be anything you wish it to be.

please read the NIST publications which define the Avoirdupois pound in
terms of kilograms. this is not debateable since NIST is *the* authority in
the US.

gravity wrote:

> please read the NIST publications which define the Avoirdupois pound in
> terms of kilograms. this is not debateable since NIST is *the* authority in
> the US.

The NIST publications define the numeric conversion factors, not the
legality for use of any particular terminology.

The approximate conversion factor for a pound (mass) is 0.4535924 kilogram.

The approximate conversion for a pound (force) is 4.448222 newton.

The gravitational acceleration, small g, is defined as exactly 9.80665
in SI units, but it is not similarly defined in inch/pound units.

Interestingly enough, however, is that the ratio of pound-force per
pound (lbf/lb) (thrust to mass ratio) is exactly converted to newton per
kilogram (N/kg) by the factor 9.80665.

The position of the US Government can be summarized from the following
excerpt found in Federal Standard 376B, Preferred Metric Units for
General Use by the Federal Government.

In the intro to the section on mass there is a note that says,

*** There is ambiguity in the use of the term "weight" to mean either
force or mass. In general usage, the term "weight" nearly always means
mass and this is the meaning given the term in U.S. laws and
regulations. Where the term is so used, weight is expressed in kilograms
in SI. In many fields of science and technology the term "weight" is
defined as the force of gravity acting on an object, i.e., as the
product of the mass of the object and the local acceleration of gravity.
Where weight is so defined, it is expressed in newtons in SI. ***

The document then goes on to show many conversion factors from both
pounds (mass) and pounds (force) to SI units. No indication that one is
more legal or correct than the other.

Soooo, use pounds any way you wish; just do the math correctly.

Doesn't it fail either by flashover or exceeding its permitted
temperatures?

If so then you will need to know the frequency, SWR, loss, duty cycle
etc to work it out, won't you?

Every winter here in New England we run numerous experiments, every time I walk across the living room and touch a metal door knob.

The US military has an ESD specification of 25 KV @ 5 KOhms from a healthy capacitor as a simulator.

Electro static discharge on antennas has been around for years. It is real!

Dry Climate and Wind are all that's needed. Now, is the Physics at the air molecule level [Oxygen, Nitrogen, etc.], ionized Oxygen or Nitrogen atoms, charged dust particle level [that just begs the issue ... how did the dust get charged?], Van De Graff level, etc.? Who knows?

But, the antenna ESD is a very REAL effect. You can hypothesize the cause all day. To solve the problem at the system level, I added an ESD bleed into my antenna switches.

I'm going to filter this thread to the circular file.

The application of IQ that MENSA and others use to differentiate themselves from others has been controversial for years. IQ was originally intended as a statistical tool to describe a population of students. There are many measures of intelligence and many IQ tests. Most have been roundly criticized as culturally biased or inappropriately applied.

MENSA is the queen bee of this sort of thing.

Here's some interesting quotes from:

http://www.esda.org/basics/part1.cfm

"Virtually all materials, including water and dirt particles in the air,
can be triboelectrically charged."

"When a conductive material becomes charged, the charge (i.e., the
deficiency or excess of electrons) will be uniformly distributed across
the surface of the material. If the charged conductive material makes
contact with another conductive material, the electrons will transfer
between the materials quite easily. If the second conductor is attached
to an earth grounding point, the electrons will flow to ground and the
excess charge on the conductor will be "neutralized."

"Electrostatic charge can be created triboelectrically on conductors the
same way it is created on insulators. As long as the conductor is
isolated from other conductors or ground, the static charge will remain
on the conductor. If the conductor is grounded the charge will easily go
to ground. Or, if the charged conductor contacts or nears another
conductor, the charge will flow between the two conductors."

You are free to alleviate your ignorance by reading the same
technical material that I have read or continue your present
path and choose to remain ignorant.

For instance, seems to me the Electrostatic Discharge Association
knows something about charged particles that you don't know.

http://www.esda.org/basics/part1.cfm

"Creating electrostatic charge by contact and separation of
materials is known as "triboelectric charging."

"Virtually all materials, *including water and dirt particles
in the air*, can be triboelectrically charged."

Seems the Electrostatic Discharge Association is in complete
agreement with the 2000 ARRL Handbook:

"Precipitation static is an almost continuous hash-type noise
that often accompanies various kinds of precipitation, including
snowfall. Precipitation static is caused by rain drops, snowflakes
or even *wind-blown dust*, transferring a small electrical charge
on contact with an antenna."

some old grain elevators have blown up because of static charge.

Grain has power and is electric, at times.

Moral: Eat more grain.

You got it slightly wrong.
We mostly relate cases based on our experiments, which are repeatable and unbelievers could easily duplicate them and see with their own eyes/ears/whatever instead of "theorizing" here why "it can't be".
On insulting Tom, why don't you look up the threads and see who is insulting first, pontificating and parading his "theories" on the web pages and if questioned or debunked, takes of after wives, brings Dr. Phil, etc..
Interesting that bunch of baloney on his web site gets pass and is proclaimed as gospel by his worshippers, while debunking gets attacked and smacked with personal comments about .... Are you drinking the same Koolaid?
Shield is the antenna, riiiiight! Current along the loading coil is always the same, riiiight!

4353. 5/8 wave for 20 meters

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-19 23:25:31 UTC
From: Rob Roschewsk <nospam@nospam.com>
Message-ID: <L5udnebjnJfxrwrZnZ2dnUVZ_qmdnZ2d@comcast.com>
Source record: 57595

Hi gang,
I'm trying to think of a new antenna for 20 Meters. Had a thought of a 5/8 wave vertical up the side of the house. My calculations tell me this would be about 41+ feet. Couple of questions:

- is this a good idea?
- can I do it without radials, I'm thinking ground stake, inductor, 41 feet of wire straight up, tapping the inductor at the 50 ohm point with coax.
- I attempted to model this in NEC2 and for 5/8 at 20M I'm getting an impeadance at the base at about 7.4613E+01-4.3625E+04j. Does that seem likely or is my model broken?

Looking forward to what you all think.

Thanks,

--> Rob

>
>
> And how much power can RG58 take?

Now that is something I can answer. Or at least I have found charts
that give me values for that. Assuming you can trust them, rg-58 can
handle 300 watts at 50 Mhz and 160 watts at 150 Mhz. Times microwave
equivalent LMR-190 says it can handle 680 watts at 50 Mhz and 390 at 150
Mhz. It also has the following foot not on those power ratings, "Power:
VSWR=1.0; Ambient = +40ï¿½C; Inner Conductor = 100ï¿½C (212ï¿½F);
Sea Level; dry air; atmospheric pressure; no solar loading"

I have yet to find anything that tells how much power a BNC connector
can take though. I found one that gave it a voltage rating of 500V and
a current rating of 3.5A DC. If you use Ohms law 500V at 50 ohms would
be 10 amps which gives 5,000 watts, I seriously doubt it can really

handle that. That calculation probably didn't help any. If you take the 3.5A with 50 ohms you get 175 V and 612.5 watts. However that 3.5A was DC and generally it is easier to carry the same number of amps with AC, but not sure how that changes as the frequency goes way up.

In the end I still don't know how much power it can handle, but I still think it is well over 100 watts. If I were using the LMR cable (which I do) I would probably trust it up to 300 watts at 50 Mhz. With the RG-58 unless my VSWR were perfect and or the ambient temperature were pretty low, I would probably keep it down to 200 watts.

Rebar has a horrible B-H curve, and low permeability. You would do
better with a length of black iron pipe that you annealed after you
sawed a slit in it, lengthwise, to reduce eddy current losses.

i've only made one 5/8 wave. i hear a cap works well since the antenna is
overlength and thus inductive.

you need radials too. my 5/8 wave didn't do too good, i suspect too many
trees, and not enough radials.

It's what Shawn Carlson used. He also used mu metal which he got from
Scientific Alloys in R.I. Much better, but pricey.

4366. Re: Log Peridic 50m - 1300m

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-20 01:39:32 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <129ekcdilceonb8@corp.supernews.com>
Source record: 57608

Dear Howard W3CQH:
You have not been clear about what information you need. What do you
wish to accomplish?

Here is Section 207:

Telecommunications Act of 1996

SEC. 207. RESTRICTIONS ON OVER-THE-AIR RECEPTION DEVICES.
Within 180 days after the date of enactment of this Act, the
Commission shall, pursuant to section 303 of the Communications
Act
of 1934, promulgate regulations to prohibit restrictions that
impair a viewer's ability to receive video programming services
through devices designed for over-the-air reception of television
broadcast signals, multichannel multipoint distribution service,
or
direct broadcast satellite services.

It sure is not clear what this has to do with what you have said so far.

..... and, in "real" engineering: Kg is the unit of mass in the SI mks
system. Newton is the unit of force. F does equal MA (at least for low
velocities).

Tom Donaly wrote:
"There`s no such thing as a clear-skycharged-particle problem, either in the Arizona desert or anywhere else."

I believe there is from countless observations at AM broadcast stations I`ve worked in over a period of many years.

The insulators used to break up the guy-wires flash over with "bangs" on certain clear windy days. This might be no problem except it becomes so severe at times that it overloads the transmitter, taking it off the air momentarily.

Flash-overs of the guy insulators occurs in S.E. Texas where the humidity is often very high by most standards. Each guy has many insulators in its length and double insulators at the guy attachment point to the tower.

Best regards, Richard Harrison, KB5WZI

it's my understanding that you can use steel because the frequencies are
very low. however, i plan to research this further.

one thing i'm not clear on is coil diameter and air core. every dollar
spent on a metal core could be utilized for more turns for the antenna. and
i'm not sure if a big coil would have better aperture and gain than a small
diameter.

one thing i'm noticing is that there are basically two types of antennas.
one type is built by amateurs and is basically guesswork or based on prior
designs. the other type is built by professionals, often doing research in
earthquakes.

A high permeability rod intercepts flux from a volume of space a
little less than a sphere with a diameter equal to the rod length. An
air core (short length to diameter ratio) coil intercepts flux from a
volume of space a bit larger than a sphere with a diameter equal to
the diameter of the coil. The air core coil has the advantage of
being relatively light and cheap. The iron core rod takes up a little
less space, and allows the coil to be electro statically shielded a
lot easier. It also produces the the same inductance with a much
shorter length of wire, so, for the same gauge wire, the coil
resistance is lower. With good winding technique, I think the stray
capacitance can also be lower. If the coil is wound on a tube, you
can also try different cores with little effort.

http://www.esda.org/basics/part1.cfm

Take a look at Table 2 where humidity is taken into account.
The static voltages at low relative humidity are magnitudes
higher than the voltages at high relative humidity. It certainly
can happen at high humidity but low humidity makes the problem
magnitudes worse.

Either a series coil or a grounded tapped coil will work. Radials are a
must.

I am not a HAM but my brother is. The main reason they came up with the idea of
the no code license was to spark interest in Amateur Radio. The hobbie is
getting to be near extinct in the 21st century compared to the interest of the
1950's to 2000.

The NIST isn't the authority on the laws of physics. One of the most
basic of which is F=MA, if you use pounds for mass in that formula you
get the wrong answer. Nothing that NIST says will change that.

200 lbs = 6.25 slugs * 32 ft/sec^2. Using pounds, the formula won't
work any other way.

5 WPM is do-able! My 4 1/2 year granddaughter copies 5 wpm! Her 10 year old brother, who learned it in Cub Scouts, taught her. And, she can't even spell yet! But, she knows the alphabet from watching TV.

Some people have DIFFICULTY learning Morse Code, real difficulty!

I have taught Morse Code off and on for 40 years and from total ignorance to 100% success in 8 hours, 2 hours a week for 4 weeks [plus a little home practice. It is practice [work] that makes it successful.]

Some people can learn the code but suffer from "TEST STRESS". They can copy it comfortably in their home or their surroundings; but, when they have to demonstrate that skill in front of a 'WITNESS' who has pass/fail power, they tense up and fail. That's understandable and can be worked with.

Some people are dyslexic. But, they can hear it and talk it out, but can't get it on paper. But, they learned the code.

If you can learn the english alphabet, if you can learn the english language, if you can read this email then you CAN LEARN Morse Code at 5 WPM. You may never progress to 20 wpm [It took me 24 months at 1 hour of practice a day every day to progress from 5 to 20 wpm] but 5 wpm can be learned.

Teaching methods, practice criteria and testing/verification methods become critical for those with difficulty.

I'll top post again for brevity and getting to the point.

I like CW! It is most likely going away as a requirement. I'm sad at this.

Amateur radio will change as a result. Everything changes. Hopefully the changes will be positive.

Thanks to all for the feedback.

So I'm guessing radial are a must for any vertical.

If I want something made of wire, and omni directional what would be my
best bet? Inverted-V ?

>That's needlessly insulting.

No, it's a statement of historic fact, as determined by the licensing
authorities. But it's incorrct -- anyone who can't copy 5 wpm deserves a
license, but it's Citizen's Band.

A further valid statement would be that anyone with an IQ approaching 100 can
learn to copy 5 wpm. That's less than one character every two seconds, which
gives tons of time to recognize and write the single character before the next
one begins. Dyslexia cannot apply, unless it is dyslexia that affects the
remembered dot/dash pattern of a single character.

the inverted vee sucks. you might want to read the Cebik article, and make
sure you avoid tight angles.

i used inverted vees for a few years. one was 100', another 130'. they
seemed to have some gain in random angles. they seemed to be an NVIS
antenna on the low bands.

i would recommend a dipole. you will get nulls.

Cecil,

Once again you have managed to complete encircle the issue with useless factoids while avoiding the key question.

I doubt that anyone reading RRAA has a problem with understanding static electricity. Similarly, it is unlikely that anyone here will deny that "noise happens."

The question is: What causes the noise, "precipitation static" or "corona"?

You have claimed without any support whatsoever that the air cannot be ionized under your "dry" conditions, and therefore corona cannot exist. At the same time you offer references from the ESDA that show charging of particles up to 20,000 volts or higher.

Do you suppose corona cares whether the air molecules themselves are charged or whether the unbalanced charge is held on these highly electrified dust particles?

For my qrp rig, I'm using an end-fed wire, sorta L shaped, going up
about 20 feet, then horizontal. It's 3/4 wavelength long for the low
end of 20, attached to the random wire terminal of my tuner, with a
single 1/4 wave counterpoise attached to the ground of the tuner. A
few twists of the tuner inductor, and it sees pretty low swr. Not sure
I would try this with high power, but at qrp levels it doesn' seem to
be a problem, bringing the antenna into the shack.

Tom Donaly wrote:
> You could be right, who knows? Certainly not the people who
> are afraid to experiment.

No need to reinvent the wheel when all the experimentation
in the world has already been done. There have been many
experiments performed concerning "fairweather phenomena".
(Thanks Jim) A Yahoo search turned up hundreds of references.

"Atmospheric Electrostatics" is a 120 page free book
available for downloading at:

http://www.colutron.com/products/cosmos.html

Here's a quote:
"In contrast to rain, precipitation currents carried to
ground by snow are usually always negative under
potential gradients between +/- 800 V/m (Chalmers 1956).
The total precipitation current around the earth is
estimated to be about +340 amperes."

Changing the subject away from charged water/dust
particles: One of the items that W8JI has been calling
"corona" is not corona at all. It is called the "electric
fairweather field" which is NOT corona. Corona requires
an ionizing current of 100 uA per cm^2 for as long as
the corona persists.

jesus, let's just do away with the written test *and* the CW test. let's just open the doors to anyone. we'll set up a webpage at the ARRL site, and you'll just point and click. it will be as easy as becoming a Reverend.

you could license your dog, a terrorist, anyone.

honestly, i am very glad there are minimum requirements. this keeps out people who are not serious about the hobby. people who don't know what they are doing should not be transmitting (esp on HF).

this whole CW debate is what we call the dumbing down of America.

i mean we have minimum standards for driving in America or becoming a citizen, why is ham radio so different?

> electrified dust particles?

Corona requires an ionized path through the air with
a sustained current of 100 uA per cm^2. What you are
calling corona is not corona. If a charged particle
is not in the act of discharging, by definition it
cannot be corona. On a clear dusty day, where is the
ionized glowing path through the air that necessarily
accompanies corona?

What W8JI has previously been describing is the electric
fairweather field, not corona. Please see:

You take an average lady to a nice restaurant and engage
in small talk while buying her dinner and a few drinks.
If she likes you well enough, she will go home with you.

The only difference in MENSA ladies is that they don't
like small talk. :-)

I would center feed it with horizontal ladder-line
and use it on 20m-10m.

However, a 1/4WL sleeve on the bottom half would
allow you to feed it at the bottom with coax.

Another possibility is a matching network at the base.
Your ground rod might work OK with that.

> too stupid to pass one.
>

NO! Don't label another person! It is wrong to label! Particularly when you do not know any of his/her life's circumstances.

I said some people have difficulty learning or learning one particular subject.

It is reported that Albert Einstein had difficulty learning Calculus. The man was a Physics genius but needed help with advanced math.

I hold a degree in engineering and have completed four years of seminary, but I have not been able to learn conversational SPANISH. [About two years after ordination the Cardinal requested that I learn Spanish at the seminary . After two months the instructor approved my withdrawal from the class. I could learn vocabulary, how to read, write and the grammar for spanish, but my ear does not hear spanish. Total immersion in a Spanish speaking community would be the way for me to learn.]

I still say, anyone who can learn an/the alphabet can learn Morse Code. For those with difficulty, the solution to the issue is teaching METHODs not the student's difficulty. Any alphabet is recognizing sound patterns. Words are simply combinations of sound patterns.

For 'an_old_friend' I would begin by teaching an alphabet of SOUND PATTERNS. No requirement for speed. Just focus on sound patterns. Keep it very simple. Each two hour lesson would focus on no more than 7 letters until well heard. Then move to SOUND PATTERNS that are close to or similar to those [s]he has learned and is mastering. [Example: learn the sound patterns for 'A', 'W', and 'J' repeat until they are instantly recognized. Then move on to 'N' 'D', 'B', etc. Don't count 'dots' or 'dashes' but hear sound patterns.]

The next two hour session, one week later, would begin with a review then add 'T, M, O' followed by 'E, I, S, H'. Drill sound patterns. Then end the session by sending simple words using the 1/2 of the alphabet that has been studied. Speed is NOT a requirement! Accuracy is! If Farnsworth timing at 18 wpm is a roadblock, then change practice timing to 13 wpm or 10 wpm or 7 1/2 wpm or 5 wpm or 3 wpm. SPEED is NOT a REQUIREMENT! Accuracy is!

The next two weeks complete the alphabet. Week five would include the numbers and common punctuation. [5 sound character patterns and 6 sound character patterns].

Having said all this, my defense of CW is not any legal requirement. It is simply the best way to work rare DX. Much less power required. Much less bandwidth required. Much more discernible [copyable] in a pile. And, it is fun!

it was differential geometry that Einstein was unfamiliar with. when formulating relativity, he realized that he needed tools that he was not familiar with. so he went to a mathematician friend and learned which tools he needed.

please understand this in the context of 1912. differential geometry was fairly new back then, i believe it came from Riemann.

it's possible for some branches of math and physics to be relatively arcane. for instance, de Borges attempted proofs use operator theory. most mathematics students cannot read his papers. in fact, most professional mathematicians can't read them either. the only reason that de Borges proof of Bieberbach became accepted is that it was rewritten by other Europeans.

it's not uncommon for a theoretical physicist to have to learn a new branch of math to solve a problem. for instance, string theorists working on the landscape turned to statistics.

fun for you the migraine headaches I get listening to any of it is not
fun none enjoys pain on that level

yes I might be ableto learn well enough now with only a receive or
tranmited test (and if I were going to try it would be to send) so I
don't have to listen to it

you have fun with fine go for it
Bear in mind I think Mose and esp the attiudes around are bad for the
ARS but I support your freedom to disagree and even to just do
something I consider nonproducitve just for sheer joy of it

I expect the same however for myself

relativity utilizes tensor calculus, which is a few semesters beyond the basic integral calculus taught to many college students. even today, relativity is viewed as fairly knotty. general relativity really isn't tackled until graduate school.

it's my understanding that Einstein was very good at math. to be a lowly patent clerk and revolutionize physics requires real skill.

what is advanced math? multivariable calculus and ordinary differential equations are viewed as advanced by the general population, however millions of people have learned the basics of these. in contrast, there are papers in number theory that can only be a read by a dozen people on the planet.

it's partially due to our own limitations as humans.

So that would give a current of about 0.06 picoamperes per square foot?

The sleeve idea sounds interesting.

Could I build it out of say aluminum tubing, run the coax up the center
of the tube to some sort of insulator, shield connected to the braid and
center connected to a wire extending upwards? Could I build the top half
out of tubing as well or does the radiator need to be significantly
smaller than the sleeve?

Yeah, you discovered why they* suggest using an array of values of bypass capacitors, even when using SMT capacitors with "zero" lead length, to do a good job of bypassing a supply over a wide frequency range. And why even in ham construction literature from the 1950s they talk about keeping leads very short for good RF construction.

Cheers,
Tom

* Some will argue with using different values because it can lead to unwanted resonances. But those who do it right, by using several values with no large ratio from one value to the next, get very good bypassing by using multiple values.

Cut two 1/4WL sections of tubing. Slip one over the coax and
connect it to the coax braid where the coax enters the
tubing. Leave the outer insulation on the coax. Don't connect
the bottom tube or the coax braid to anything where the coax
comes out. Install an insulator/support to hold the two pieces
of tubing together in a straight line dipole-like configuration.
Tie the coax inner conductor to the upper tubing. With this
configuration, you won't need additional choking on the feedline.

```
******************* ********************+
| ====================+========
1/4WL +--------------------------------- coax
| ====================+========
******************* ********************+
```

*** is the tubing, + is a connection.

And just one of the many reasons I keep saying that good RF measurements are much more difficult to make than most people realize.

I don't understand how this would work. The tube to coax connection on the right seems to extend the 1/4 wave tube indefinitely, down the line. I think I would connect the coax shield to the right tube at that tube's left end, and add a ferrite current balun around the coax where it exits at the right end of that tube.

Now that you mention it, neither do I. I just copied it from
the 1993 ARRL Handbook, Fig. 3, on page 14-4. I do know how it
works when feeding a balanced antenna. Let me redraw it with
one that I know works.

As one who is dedicated to making equipment that enables making good RF measurements, I say, "Amen, Brother Roy." One of the problems, if you will, of modern test equipment is that it makes it LOOK like it's easy to make good measurements, but you would be wise indeed to think instead that the equipment operation is easier so that you can spend your time making sure that your measurement setup is appropriate to the task, and so that you can make measurements in multiple different ways as a double-check or triple-check with less effort than you might have used before to make one uncertain measurement.

Only slight topic drift: it's rather like trusting SPICE (or other simulator) to give you the right answer without understanding either SPICE's limitations or your model's limitations. Properly used, SPICE is a great tool. Improperly used, it will give you some very bad answers. Neither SPICE nor modern test equipment is a substitute for using your head--but both can free you to use your head more effectively and creatively.

Cheers,
Tom

Markie comes up with a rationalization of his spamming. Too bad it's
like him, seriously flawed.

4440. Re: Sky noise temperature - 2m, 70cm, 23cm

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-20 18:47:26 UTC
From: K7ITM <k7itm@msn.com>
Message-ID: <1150829246.594449.283790@y41g2000cwy.googlegroups.com>
Source record: 57482

I only scanned the replies so far, so may have missed a similar reference, but recent editions of "Reference Data for Engineers" (used to be ITT Reference Data for Radio Engineers) in the "noise" chapter have a couple "Radio-sky maps," one for 136MHz and one for 400MHz. There's a great deal of variation, depending on where you point your antenna (assuming a very narrow beamwidth). On 400MHz, at about 18 hours RA and -30 degrees declination, you'll get about 280 kelvins; at 10 hours and +30 degrees, you'll get about 15 kelvins. On 136MHz in the same two directions, it's about 3600 and 200 kelvins. Perhaps such sky maps are available online somewhere for a wider range of frequencies.

Cheers,
Tom

Cecil,

None of those references mention world peace or noise on HF antennas either. What is your point? There is an entire universe of documents that include no reference to corona.

I will repeat, nobody has any issues with fairweather fields or any of the other atmospheric stuff you keep dredging up. So what?

You have not offered a single reference beyond the ARRL Handbook that supports your model for noise generation.

73,
Gene

So you're saying CB'ers have more pull because there are more of them? Hmmm.
You might be right, but we're dealing with President Bush here. He don't
listen to Lazy Stupid people. If listened to what Lazy stupid people wanted,
we'd be cutting and running from Iraq like the Democrats want and he ain't
cutting and running.

There's still hope. Send that email. Save amateur radio and shortwave.

Earl

So what is your point? Is it that CBers are stupid? Or is it that CBers vote
democrat?
If Bush didn't listen to "Lazy Stupid" people, we would not even be in Iraq.
Maybe you missed it when they never found any WMDs in Iraq, which is why we
went to begin with. He obviously listens to "Lazy Stupid" people, like
Russian intelligence. I'm sure if you try hard enough, he will even listen
to you.
Before you label me a liberal, I voted for Bush

No it isn't.

Some things in life require you do a little work to enjoy their benefits.
You don't want to learn CW, you shouldn't be allowed on ham radio.

And Five words per minute ain't a code test. I can fart five words per
minute. Anyone that can't learn 5 wpm is either lazy or a tard and should
stick to CB, FRS, and cell phones.

We gave those Techs the no code license because some said they weren't
interested in HF and wanted the freedom experiment with new modes, but
that's not what happened. All we got was a bunch of appliance operators
plugging up repeaters. Maybe only two or three percent are doing digital,
new modes, satellites, scatter, aurora, DX, etc. everyone else is gabbing
on a microphone like CB'ers waiting for the FCC's R & O to come out.

Particle discharge makes radio static noise.

Look at Terman`s description of "precipitation static". Instead of charged particles blowing in the wind and alighting on stationary antennas, Terman describes aircraft and their antennas flying through clouds of charged particles. The effect is the same.

Terman`s solution: keep the antennas away from sharp points on the aircraft which tend to noisly discharge the aircraft, insulate antenna wires, and put Faraday shields on the directional antenna loops.

Best regards, Richard Harrison, KB5WZI

Hi Richard,

You skipped the most interesting part in Terman.

In the 1955 edition, page 857, he says,

"The term precipitation static denotes a type of interference frequently observed in an airplane passing through snow or rain. Under such circumstances, the airplane may become electrically charged to such a high potential with respect to the surrounding space that a corona discharge breaks out at some sharp point on the plane. The interference that this corona discharge produces with radio reception, termed precipitation static, is particularly serious at short-wave and lower frequencies."

So who are ya gonna believe? Terman? the ARRL Handbook? Cecil? Tom R.?

73,
Gene

a PDF reference

http://tinyurl.com/h4o6u

I've done a bit of googling on the subject, and find that most seem to favor this sort of explanation of the phenomenon. A notable exception is W8JI. To Tom's credit he performs some experiments along those lines. I'm not completely sure that I buy the conclusions, but I'll digest them a bit more. I would suggest that Tom may want to experiment with charging dust particles with that HV source rather than water.

Some have suggested that Cecil's statements are invalid because he hasn't done the experiments - not so. His view represents the mainstream. The debunkers have the burden of proof.

Corona causes RF noise for sure. But RF noise also occurs in
the complete absence of corona. RF noise in the complete absence
of corona is what we have been discussing. *Nobody* is arguing that
corona doesn't cause RF noise. We are arguing that RF noise can be
caused by something other than corona.

Yep, here's a quote from the mainstream:

http://www.esda.org/basics/part1.cfm

"Virtually all materials, including water and dirt particles
in the air, can be triboelectrically charged."

Given charged dirt (dust) particles encountering a bare-wire
dipole, all the rest is simple physics.

Well, Larry, it took you to the last sentence, but you did actually lurch
into the problem.
Within seconds after learning what dah-dit-dit-dah means (or
dit-dah-dah-dit, for that matter), I fail to
accurately recognize them when they are sent again. Hundreds of tries --
all failures, all mine.

From your lofty perch, as a successful Morse Code user, you look down on me.
You could stand to learn a
little humility. It would serve you and the amateur community better than
dah-dit-dah any day.

Stability? Frequency accuracy? Phase noise? Output power? Sweep
capability?

There's a big price difference between synthesized and non-synthesized
rigs, as well as operational differences. Do you *need* the ability to
set the operating frequency easily, repeatedly, accurately? That may
point you to a synthesized/pll rig. But if you don't, such as doing
sweeps from about here to about there, non-synthesized rigs can do
fine.

Figure out what you *need* in terms of specs, and start looking around.

I'd say plenty is available for under $1000.

Wavetek 2002 for $200 on eBay -- that's good to 2.5 GHz. It's also a
sweeper. Other places have the 2002 for $100 up.

Or you can spend more money for HP/Agilent and get HPIB (remote
programming), stability, lower noise.

Wiltron 6647 on eBay, goes from .01 - 18 GHZ, for around $500, a
sweeper.

HP 8620C with 86222B, .01 - 2.4 GHz on eBay currently for under $200.

The "boys at Langley" don't wield power to think and act anymore. Your VP has seen to it that his own boys in the Pentagon have taken over that business. Kill the messenger. Langley had it correct when they said Iraq didn't have WMD. That's what go Wilson in trouble, remember?

Mike,

Did you actually read the reference you provided? It offers complete
support for Tom's position and zero support for Cecil's position.

As usual around RRAA, this entire matter has morphed into all sorts of
side issues. The original and only point of controversy is whether the
so-called "precipitation static" is related to corona discharge or
rather to some sort of particle-by-particle charge transfer of the antenna.

Cecil claims that corona cannot exist in "fairweather" conditions, although there is no reason given. Therefore the particle-by-particle hypothesis is the only reasonable choice as the noise generator. The ARRL Handbook seems to go along with that idea, although not very explicitly. Other references, including Terman and the training document you provided say that corona discharge is responsible for the noise generation. W8JI agrees with that hypothesis.

Actually, when it comes to some of the issues raised on this newsgroup,
yes, I do. I don't see why I should believe what Cecil makes up in his
head just because he makes it up in his head.

"I can't believe _that_!" said Alice.
"Can't you?" the Queen said in a pitying tone. "Try again: draw a

long breath, and shut your eyes."
Alice laughed. "There's no use trying," she said: "one can't believe impossible things."
"I daresay you haven't had much practice," said the Queen. "When I was your age, I always did it for half-an-hour a day. Why, sometimes I've believed as many as six impossible things before breakfast. There goes the shawl again!"

Cecil and the White Queen would get along well together.

It doesn't represent the mainstream. Go back and actually read the
references. Besides, if Cecil can't demonstrate the validity of his
views experimentally, even if there are some sources that agree
with him, he's just parroting the old wives.

should we get rid of the written test because people can't learn decibels
and basic algebra?

perhaps the CW test could have a question pool similar to the written. you
could memorize all the answers. i am actually dead serious. or standardize
the test so that the output is always like a QSO in super morse. there are
ways to make the test easier.

hmm, or we could have an option that you can view the CW in a spectrogram
and decode it visually.

I cannot find any support for Tom's position except from
wishful thinking by a certain group of ignorant people here
on r.r.a.a.

> As usual around RRAA, this entire matter has morphed into all sorts of
> side issues. The original and only point of controversy is whether the
> so-called "precipitation static" is related to corona discharge or
> rather to some sort of particle-by-particle charge transfer of the antenna.

Yes, and the references I have provided indicate that natural
corona is impossible under clear-sky fairweather conditions.
You obviously have not read them.

> Cecil claims that corona cannot exist in "fairweather" conditions,
> although there is no reason given.

Again, obviously a false statement based on wishful thinking.
As proved by my references, the existence of corona requires
~100 uA per cm^2. Quoting from the previous NASA web page, for
the fairweather field, "the current is 10^-12 amps per square
meter."

Requirement for corona to exist:

100 uA per cm^2 = 10 amps per square meter

Available current during fairweather conditions:

10^-12 amps per square meter

Conclusion: During fairweather conditions, the current is
13 magnitudes too low for corona to exist.

> Therefore the particle-by-particle
> hypothesis is the only reasonable choice as the noise generator. The
> ARRL Handbook seems to go along with that idea, although not very
> explicitly. Other references, including Terman and the training document
> you provided say that corona discharge is responsible for the noise
> generation. W8JI agrees with that hypothesis.

Again, obviously a false statement based on wishful thinking.
Terman said no such thing about stationary antennas. The energy
for the corona referenced by Terman is coming from the movement
of the airplane, i.e. from the engine fuel. Corona requires a

supply of energy that simply doesn't exist for a stationary
receiving antenna under fairweather conditions.

If the airplane was not moving, i.e. not being supplied with
energy by the engines, the corona would probably not exist.
Comparing a moving airplane to a stationary antenna is apples
and oranges and is therefore an invalid argument.

If we supply the antenna with enough RF energy from a transmitter,
corona will surely occur. But a supply of extra energy from a
transmitter or from a moving airplane is not what we have been
discussing. We have been discussing fairweather conditions for
a stationary antenna.

Because under passive fairweather conditions, corona requires 13 magnitudes more current than is available in nature. Please see my other posting.

And just a comment on your seeming innocent question above. You seem to be asking me to prove that there is no corona discharge when proving a negative is impossible. The onus of proof is upon the one(s) who assert(s) the positive position.

W8JI asserted that there is a corona discharge and you agreed with him. Therefore, the onus of proof is upon you. Please prove that corona can exist on a receiving antenna under passive fairweather conditions.

People are free to assert negatives at any time without any proof. For instance, if I assert that you cannot dunk a basketball, my assertion will remain true until you prove that you can dunk a basketball.

Gene, W4SZ wrote:
"Cecil claims that corona cannot exist in "fairweather" conditions, although there is no reason given."

My broadcast station experience includes blue-skys in advance of thunderstorms when guy-wire segements became so charged that the compression insulators separating the guy segments would flashover with loud bangs. These times would be windy. My conclusion is that charged air particles (ions) strike the guy wires charging them to high but varying potentials.

The arc or flashover between segments is a corona of short duration, not St. Elmo`s fire. It sounds like a gun shot. These may become so numerous that the sounds are as if a battle were occurring. The sounds are not unlike shorting the leads of a highly-charged large capacitor.

If leakage across the insulators were fast enough, rhere would be no bangs.

Best regards, Richard Harrison, KB5WZI

you raise a good point.

first of all, Tom is wrong. not much of anything can be proven. in mathematics, you proceed from axioms, which are accepted assumptions. then you chain things together to result in proof. some proofs are more formal than others.

Russell and Whitehead attempted to axiomatize mathematics, which resulted in failure. Russell never did serious math again. Tom should read the work of Godel, Chatin, and Turing.

in M-theory (strings), there are many things which can't be proven at this time, and may never be proven. there are some experiments which never can be performed. this why we say string theory is unfalsifiable.

so toss out this idea of "proof", because it's a just a term that engineers think they know something about.

and i didn't even get started on epistemology.

I spoke to a friend of mine who works in the archery business (Parker Bows),
and he says that hollow fiberglass is almost non-existant now. Everything
has switched over to carbon fiber tubes. He says the blanks are about 32"
long before being made into arrows, so that might limit their uses.

It matters not. When management lacks the same talent, engineers will
be chosen for economic rather than practical reasons. Outsourcing to
India and H1B visas are proof. The fact that India has yet to produce
a single Intel or Microsoft or H-P or Sony is lost on those whose who
fawn over those rote trained hordes.

If nothing can be proven, then how do you know I'm wrong? Besides,
it isn't a question of whether or not I'm right. It's a question of

whether or not to believe the fantasies of people who are unwilling to examine Nature. If you've really read and understood the mathematicians, you'd know that few, or none, of them care the slightest about the real world. It now seems that some physicists - the string theorists - have decided to move to Cloud Cuckoo Land (See Jonathon Swift) so they can live in a nice, comfortable world of well-paid solipsism, confident that a theory that is incapable of proof, is also incapable of disproof.

Maxwell thought up Maxwell's equations, Cecil, you didn't. Heinrich Hertz, Farady, and others did the experimentation. Besides, you only have to turn on your radio to prove the equations valid. Even Maxwell knew that without experimental proof, his fine mathematics was only idle speculation.

C'Mon Tom,

Cecil's objective is NOT about technical discourse, it is about having more posts than others and seeing his name responded to as hits. Of the last 212 posts, 87 are his and there are 13 other posters to share barely an average of 10 each.

You are responding to Cecil's usual forced expectation of others proving a body of science before he proceeds to measure something he maintains is commonly observable. His demands:fulfillments far exceed his 9:1 posting frequency.

So, as this is actually nothing new, it remains that his postings serve only the purpose of entertainment. Those that confuse them with insight or balanced correspondence (or believe in quantity = quality) are beyond hope.

No, he didn't say. Sorry.

I suspect they're not generally available. From what I've heard before,
these are made with their super secret process, and each manufacturer is
slightly different. Not important when making an antenna, but the bow
hunters have their preferences.

you can restate most negatives as positives. an example of this is a logical statement, in which case the contrapositive is always true. if P, then Q. if not Q, then not P. another example is Demorgan's theorem in set theory and electronics.

if you say that general relativity is wrong, the burden is on you to prove otherwise.

if the corona discharge theory is held by 90% of physicists and engineers, then anyone with a charged particle theory (a minority viewpoint) must do experimental verification or formulate a theoretical model.

in this case, i think that both Cecil and others should cite peer reviewed articles.

Aha, so you don't even follow your own advice. I quote conventional wisdom from the last 100 years of physics research and you ask me to to prove it experimentally.

Why do you try to hold me to a higher standard than the one to which you hold W8JI and yourself? Everything I have reported is old hat to competent physicists and competent engineers who know anything at all about atmospheric physics.

What you and others have asserted goes against 100 years of conventional wisdom and thousands of experiments in the field of atmospheric physics during those 100 years.

In fact, the only way to win your argument now is to prove that a Corona God really exists and is in control of fairweather fields.

100% of physicists and engineers hold the corona discharge
theory. 0.1% of posters to r.r.a.a seem to hold that corona
discharge is the only force at work in the entire universe
and caused the big bang. :-)

99.9% of competent physicists and competent
engineers know that corona is not the only cause of RF
noise. Unfortunately, r.r.a.a. has more than its fair share
of people who deny the past 100 years of scientific experimentation
and research into atmospheric physics and stick with their Corona
God religion.

Other assertions by that same new-world anti-conventional
wisdom crowd:

Reflected waves contain zero energy and are not the cause
of standing waves.

Standing-wave energy just sloshes from side to side in a
transmission line.

The distributed network model is gobbledygook.

Lumped-circuit analysis never fails.

There is zero delay through a real-world 75m bugcatcher coil.

Charged particle RF noise doesn't exist.

You're absolutely right, Richard. Of course, if he can use all of
his rural debate tricks to get people who disagree with him
into abandoning the thread, then he thinks he can claim victory
as being the only combatant left on the field of honor. Notice how
he used the Mensa Society post to destroy the discourse? Cecil isn't
really serious, as you point out, and his posts are only valuable for
their entertainment value, as you also point out, but there are,
alas, people who are soft-minded enough not only to take him seriously,
but to agree with him as well. I think Roy had the right idea when
he plonked him. The rest of us should probably follow Roy's example.

Cecil,

That's a good one. I believe the fairweather reference relates to the average current density over the entire earth. The corona reference (which does not even come close to being a "requirement") applies to a very localized environment. If the average current density over the entire earth increased to 100 uA per cm^2 I think it might be best to live far underground.

I have not measured currents, fields, or corona in the atmosphere, but I have some experience with high voltage equipment in laboratory environments. I can assure you that corona can occur even when there are no preexisting fields or currents in the surrounding air. High voltage and sharp emission points are quite adequate.

The fairweather current and the corona current are completely unrelated.

Cecil,

I have not said that I agree with W8JI or that corona is a necessary condition for radio noise.

What I have said is that I disagree with your half-baked fractured physics explanations.

Corona does not require ANY preexisting current, and certainly not the global "fairweather" current. The high fields near a sharp point will create all the corona current necessary.

Hi there.

Just a quick thought. I will not jump into the code vs. no-code fray. That said, I'd like to pass on an experience I had with a college professor friend of mine many years ago, now passed (Doc Bronfield WA2SMW). I learned CW at the age of 9 using flashing light. Now age 57. Got my novice at age 14 and general at age 15. The extra came easy as did 30 wpm plus CW. Not so with my friend Doc. He tried and tried, and then we realized that he had aural dyslexia. So I had an idea. With the help of local engineering types. They built a keyer that could sent different frequencies slightly for the dits and dahs. That was what he needed to get his code speed up and pass the general using the keyer during a FCC test. Here's what I believe should happen with CW. When I passed my extra there were no extra class operating privileges issued, but the FCC issued a nice Extra class certificate for the accomplishment (which I still have). I suggest we leave the 5 wpm code requirement in place as it now is, but go back to issuing the 20 wpm certificate by VE's. That would, perhaps, satisfy, the pro-code folk? It would reward the accomplishment without necessarily making it an Extra class requirement.

$400,000,000,000 and counting. Do you honestly feel safer? Not only do we have to deal with Iraq, but now we have to deal with N. Korea and Iran, situations that were exacerbated by lumping them into the "Axis of Evil", whatever that is.

He'll sell out just like all the other politicians. If the energy companies want to run roughshod over our HF with BPL, or if cell phone companies want to buy our higher frequency bands, they will. The Golden Rule: He who has the gold rules.

Alan

You can always use an active antenna.

Here's one the claims performance from
30 Hz to 50 MHz.

Hi Richard,
Cecil is impervious to criticism, anyway. As long as he can
think up "objection stoppers," as fast as an encyclopedia salesman

selling his wares to impoverished housewives, no one can get
to him.

Hi Gerry

Thanks for the reply. I was actually being lazy. I could probably have searched for a source of fiberglass tubes, but I thought I'd take advantage of your familiarity.

Jerry

It is the 340 amperes divided by the surface area of the earth in square
feet. I guess you could call it an average.

So, "much greater" than 6E-14 would be what, maybe 6E-13?

4533. FSM software update - V1.11

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-21 21:55:10 UTC
From: Owen Duffy <owen@no.where>
Message-ID: <chfj929rkea5vb2v6edn0vp0dft3ucfd1l@4ax.com>
Source record: 57475
Cross-posted to: aus.radio.amateur.misc,rec.radio.amateur.antenna

Announcing release of FSM V1.11.

FSM (for Field Strength Meter) is a software application that extends a conventional SSB receiver to allow measurement and calculation of field strength of radio signals, noise or interference. FSM is a software implementation of the technique described by Ed Hare of the ARRL in "Manual Testing of Field-Strength Levels Using Conventional Receivers" dated August 2004 .

Version 1.11 revises the algorithm for calculating receive power from the Step 2 and Step 3 measurements to increase FSM's flexibility and accuracy at lower measurement levels, allowing measurement of noise levels with Fa below 0dB.

This has allowed relaxation of some limits that were needed for the older algorithm, and an associated change to the calibration utility. Documentation has been updated accordingly.

For more about FSM, go to http://www.vk1od.net/fsm/ .

To download the installation package, go to http://www.vk1od.net/fsm/support.htm .

FSM announcements are published in the VK1OD-Newsletter. To subscribe to the newsletter, send email to VK1OD-Newsletter-subscribe@yahoogroups.com

Cecil,

You are seriously confused. The energy source is completely irrelevant.
The only issue is what causes the noise heard in the receiver.

I would also add that you must be able to prove that you can trace your ancestry back to 1776 or earlier in order to hold an Amateur Radio License as only decedents, of real Americans around at the time of the Revolutionary War, should be allowed to possess a license.

Also, that you not be allowed to operate any tube gear. It sucks too much electricity and is helping to destroy the environment.

You must build your own equipment. Ban all manufacturers of amateur gear, unless of course, it is made in America in which case a 200% tariff should be added to help fund the FCC with all this additional testing that you would now require.

All amateur operators must also pass a spelling and grammar test. They must not be overweight and have perfect hygiene and never smell at any hamfests - especially Dayton.

Once you start riding an electric cart at Dayton or any other hamfest, your Amateur Radio license is immediately revoked.

There are probably some other items that need to be added to the list of requirements, but I will submit those to these groups later.

Receiver noise has many causes. Corona is certainly one
of them. There is absolutely no argument about that.

Please provide a reference that says clear-sky wind-
driven charged dust particles cannot cause receiver
noise.

Nothing wrong with that idea. I implemented that idea when
I was in Arizona to eliminate arcing at the coax connector
which certainly reduced the noise level.

Then you probably need to go back and read the web references
that I have posted in your absence. Here's one of them:

http://www.esda.org/basics/part1.cfm

"Virtually all materials, including water and
dirt particles in the air,
can be triboelectrically charged."

Since dirt particles in the air can be charged then they
can also transfer their charges to bare-wire dipoles which
obviously causes noise.

Also, it seems to me that you have been confusing corona
with the electric fairweather field. A couple of days
ago, I posted about six web references on the subject.

Probably anyone reading this thread. On a clear sky day,
what is the source of energy for your sustained
100 uA/cm^2 corona discharge? That energy has to come
from somewhere. Where does your corona energy come from?

Another positive side of the proposal is that we could eliminate a lot
of tickets. Think how quiet the bands would be for a little
while....MUCH LESS QRM! Of course that would change when the FCC
reassigned (auctioned) those now unused freqs to the commercial users.
Heck, you could do BPL through out the old ham spectrum. There wouldn't
be enough Ham clout left to stop it. Who would even notice! Cheap
Internet! GO FOR IT ! .... IMs instead of QSOs.......Great idea.
Keep those wheels turning. You might luck into another winner of an
idea! George

Some advice:

1. Check to see the download completed properly (ie that the file has not be truncated). It seems that some clients may not warn you if the download failed for some reason. FSMSetup.exe v1.11 should be exactly 1,062,400 bytes (right click the file name in explorer and click properties to get the exact file size).

2. Scan your computer (and the download) with an up to date and effective virus scanner, there are a number of viruses that exhibit these symptoms.

If you are confident that you do not have virus infection, the file FSMSetup.exe is actually a self extracting ZIP file. You should be able to open it with WINZIP, Powerarchiver, PKUNZIP etc (if you have one), extract the files to a temporary directory, and run the setup.exe file. That will bypass the issue that you seem to have with the self extractor.

If the file cannot be opened with ZIP, it is a pretty sure sign it has been corrupted (even if the length is correct).

Dr. Nagel,

You please listen to me, I get PhD from big university. My university so expensive most American can't buy cafeteria lunch.

Long time ago, many years, I make secret lair in Bikini Atoll. American call it that, but I rename to Soong's Micronesian Micronation. It has nice ring to it.

Anyway, I build androids and mind my own business, but one day I monitor Americans and they say they blow up my island. Some missile test, but I say waste of perfectly good rocks.

I detect submarine with my acoustics, and I transmit on ELF and say "Don't blow up my island please!" But my Engrish so bad, they get confused and jam me with much megawatts. I not give up though. I build big ideograph out of bamboo, it say "Don't blow up my island thanks". But they have no analyst that read my language. I escape in nick of time in my junk ship.

look at picture, see big hole in middle of island?

NOPE! The MX missile has 100% nothing to do with the Bikini Tests! Those tests were conducted after WWII and ended in the 1950s. The MX missile initial deployment was 1985.

By today's standards, the Bikini tests were low yield [~20KT] fission devices. Today's standard is moderate yields [~300 to 500 KT] fission-fusion devices.

MX has nothing to do with Bikini Atoll.

Have fun building your androids.

Cecil,

You must have been asleep when your professors at TAMU explained basic problem solving techniques.

There is often more than one way to correctly address a problem. In the case of many electrical problems it is possible to follow an approach that looks at the energy and it is also possible to follow an approach that looks at forces and fields. Neither approach is wrong, and in the end both must consistently yield the correct solution. It is often true, however, that one approach is much easier to pursue, and it therefore will be preferred.

In this case there is no quantitative information about the sources of energy, the sinks of energy, or the transport of energy. This is not a well-bounded system in which the total energy can be easily defined. An energy-based solution is going to be hard to achieve. Stick to fields and forces for this one.

73,
Gene
W4SZ

Cecil,

Absolutely no one has stated that clear-sky wind-driven charged dust particles cannot cause receiver noise.

The entire issue is whether the charged dust leads to corona discharge or whether the charge from the dust finds it way directly through the receiver front end and into the audio system.

For some reason you seem to believe that corona can exist only in environments where strong background fields exist and not in "clear sky" conditions. I don't know where you came up with that one, but it simply is not true.

Your own favorite example of an arcing connector would seem to indicate that there is plenty of charging and voltage build-up on the antenna. If there is enough voltage to support connector arcing why would there not be enough voltage to support corona discharge from some sharp point on the antenna?

> and forces for this one.

But there is quantitative information about the
source of energy for corona. You have to ignore
that information because your corona concepts
require violation of the conservation of energy
principle. Where is the energy coming from to
sustain a current flow of 100 uA/cm^2 under a
clear sky?

Fields and forces require a supply of energy. If
there is not enough energy available under certain
fairweather conditions to support your esoteric
corona theories, then those theories are wrong.

Of course a moving airplane can cause corona. The
engine fuel is pumping energy into the system.

Of course an RF transmitter can cause corona. The
transmitter is pumping energy into the system.

Under passive clear-sky fairweather conditions,
what is pumping enough energy into the system to
cause your corona? If you were correct, every lightning
rod and antenna in the world would glow at night
under starry skies. When is the last time you
saw a lightning rod glow at night under perfectly
cloudless skies?

On the contrary, Gene, that is not true. W8JI's assertions to
that effect is what started this argument.

I have posted many web page references to show that rain, snow,
and dust particles are subject to triboelectric charging. The
fact that W8JI has never seen such is irrelevant. He never saw
George Washington either.

> The entire issue is whether the charged dust leads to corona discharge
> or whether the charge from the dust finds it way directly through the
> receiver front end and into the audio system.

Then the argument boils down to whether the noise level threshold
is *exactly* equal to the corona threshold. That means there is zero
noise until 100 uA/cm^2 starts to flow through the air accompaning
the corona. Can you appreciate how ridiculous such an argument
really is?

There is most probably a region between zero noise and corona
where noise exists and corona doesn't exist.

> For some reason you seem to believe that corona can exist only in
> environments where strong background fields exist and not in "clear sky"
> conditions. I don't know where you came up with that one, but it simply
> is not true.

Nope, I never said that. I asked you to prove that corona always
accompanies charged particle noise even under clear sky conditions.
So far, you have offered zero proof. If clear-sky wind-driven charged
particles increase the noise level from S-1 to S-1.1 do you really
expect us to believe that small amount of charge is enough to cause
100 uA/cm^2 of sustained current to flow through thin air? That is
what is needed for corona to exist.

> Your own favorite example of an arcing connector would seem to indicate
> that there is plenty of charging and voltage build-up on the antenna. If
> there is enough voltage to support connector arcing why would there not
> be enough voltage to support corona discharge from some sharp point on
> the antenna?

That's not the question. The question is given 1% of the charge
necessary to cause arcing, can RF noise exist without corona
existing? If there is just one case of charged particle RF
noise in the entire world in the absence of corona, your
argument is wrong.

I guess this is a case where one doesn't ask....he just does it!
I have a 20 Meter Hi-Q Halo-type loop (6' dia) hanging from a tree
limb about 40' high. I needed lighter weight so I used RG-58 about
75' long....well-matched at the antenna for very little SWR.
I have been using this with 1 Kw SSB peak for about 10 years with
no problems...this includes reasonably long tune-up with full carrier.

I finally got it downloaded. I am not sure why but it would only down
load about 100 to 200KB at a time. I have never had this happen before.
I have downloaded 30 MB files with no problem even on my 56K modem
all it takes is a lot of time but I never have the download just stop
and think it was over.

Anyway it is downloaded and seems to be OK now.

4571. How to model a 6:1 ratio balun using NEC2

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-22 17:17:29 UTC
From: KC2PIH@gmail.com
Message-ID: <1150996648.944802.242350@c74g2000cwc.googlegroups.com>
Source record: 57363

I am using Nec Win Plus (NEC2) to view the SWR curve of my modeled antenna. The actual antenna uses a 6:1 ratio balun. Is it incorrect to just change the characteristic impedance of the line from 50 ohms to 300 ohms to see what effect a 6:1 balun would have on the SWR values? I was just assuming that the line impedance was only really needed to calcuate SWR - hopefully I am right.

Thanks,
Scott, WU2X

Yes, but that assumes a perfect balun.

Changing the modeled line impedance to 300 ohms is correct if you really have a 6:1 transformer. But you probably don't.

The impedance transformation of a typical 6:1 balun is around 6:1 when the antenna impedance is near 50 ohms resistive. However, when it's not, the transformation can be vastly different. And the balun is likely to add substantial series and/or shunt reactance to boot. So there's no way to know what impedance you'll really see looking into the transformer unless you measure one when loaded with various impedances.

You should also know that a "voltage balun", which a 6:1 balun typically is, produces equal currents in the dipole halves, and no current on the feedline, only if the antenna is perfectly symmetrical. If the antenna isn't symmetrical (e.g. if it's fed off center), the "balun" will force common mode current to flow along the outside of the coax. This will affect the feedpoint impedance as well. See http://eznec.com/Amateur/Articles/Baluns.pdf for more information about this.

Cecil,

Why do you think there is some magic about 100 uA/cm2? You found something only slightly related on the ESDA web site and now you have accepted that number as a standard. Even if it were correct, how many cm2 are you requiring? The size of a stray wire strand on the end of an antenna is pretty small.

Do you suppose there is a fundamental difference between an airplane moving through the air and a stationary plane with wind blowing past it?

Does the wind require engine fuel?

Your energy arguments are simply irrelevant. Do you understand the meaning of quantitative? Can you quote even one relevant number in terms of watts or joules?

Finally, you might want to check your references about your requirement that fields and forces require a supply of energy.

73,
Gene

Hi Roy,

Yeah, I just started a thread a few days ago regarding current vs.
voltage baluns with respect to my OCF Dipole. I started to play with
around with modeling feedline radiation following the notes on Cebik's
page about it. Doesn't seem like its really possible to accurately
predict the SWR/bandwidth when you start trying to model feedline
radiation too.

Very carefully modeling the very simple OCF Dipole I have assuming no
feedline radiation yields a SWR curve over the HF band that is no-where
near my real world measured values. The NEC2 computed values are much
higher.

Didn't mean to imply it had to be continuous. Maybe
"source" would have been a better choice of words
than "supply".

That's no surprise. Assumptions that the feedline won't radiate and that the balun effects a 6:1 impedance transformation regardless of impedance are both invalid. Garbage in, garbage out.

That's been the downfall of many a perpetual motion proponent. A permanent magnet produces both a field and a force. So it must be a source of energy, right?

I see Cecil is at it again. Gad.

All feedlines radiate and receive noise and signals. They can't help
it.

But on 99% of occasions the magnitude is small enough to be ignored.
If it works satisfactory then don't bother fixing it!

ANTENNAS, J. Kraus, McGraw-Hill 1950, is a great reference. If you passed 'emag and difeqs' in college you should be comfortable with Kraus.

Now, I have a question: "If you passed 'emag and difeqs' why do you worry about 'easy on the brane[sic]' ? You have adequate 'brane' power.

No, I see a newsgroup clown that can't accept the fact that this man learned to succeed despite his dyslexia. Instead of offering ideas that could help him learn code you decide to insult him. You sit and whine about how ham radio is going to shit because they allow no code tech licensing and possibly doing away with code altogether. But you missed the biggest point with ham radio it was to help people. Did you help this man by offering alternative options to learn code? No, you insult him instead. It is you and your kind that will be the downfall of ham radio. Blame yourself.

Why do you find the need to boost your (lack of) self-confidence by
insulting this person by comparing him to Mark? Mark chooses to sit on his
ass sucking the entitlement system dry and contributing nothing to society,
while this person decided to make the best of his what God gave him and he
contributes to the same entitlement system that Mark chooses to deplete.

Earl you are not the Pearl of wisdom, you are the faux Pearl that trolls to
enhance your (lack of) self-esteem.

Something I just thought of at the spur of the moment (not to mention keeps me on topic), some disabled person should sue to remove ALL code requirements, or offer an exclusion to those with disabilities to not have to take ANY code test under the Americans with Disability Act. I'm sure that person could even get a free ACLU lawyer to handle it.

India is not a country we rely on to build super companies (for lack of a better term). Take a look at what we send to India. Toxic chemical factories that would be choked to death by special interest groups and politicians. We also outsource technical support, which is a waste of time and money, good thing companies don't pay them much, but it's a cheap way of saying "we have tech support" without truly having it. Look at the shoe mfg. industry, all moved to third world slave labor countries. Good for the shoe industry as they no longer have to deal with unions and we keep management and development in countries that have the talent and resources to maintain state of the art products. Look at how the auto industry has changed. They sent 1000s of jobs overseas to cut down on union labor (with management and R&D in the US), and the Japs are opening plants in the US (with management and R&D in Japan) that will never deal with the UAW. I could go on forever with this post (and talk about NAFTA), but will end my rave at this point. BTW, changed subject header as it didn't seem to fit. I would have trimmed a few NGs but am unsure what groups you are subscribed to.

Accusing me of saying something I didn't say is standard
procedure for you, Roy. Why must you stoop to such behavior?
Why not argue the technical issues on the technical merits?

My meaning was that a field or a force requires energy for
them to exist in the first place. I did NOT say energy could
be extracted from fields and forces. Please stop misquoting me.

There was absolutely nothing said about signal in that entire
thread except when you tried to introduce it as a diversion.
The entire thread unfolded as if no signals existed and we
were only interested in measuring and dealing with the noise.

But now let's allow signals to be introduced into the thread.
My dipole was arcing once per second at the coax connector.
I couldn't hear any signals. I estimate the signal to noise
ratio under those conditions to be zero. Would you disagree?

I modified my dipole into a folded dipole. The arcing ceased
and I could then hear signals. I estimate the signal to noise
ratio was not zero any more. Would you disagree?

I really question the IQ of anyone who asserts that eliminating
arcing in a system doesn't reduce the noise. I assume you are
not a member of MENSA. :-)

So you are dissipating about 4W per foot of cable with key down 1kW CW. Average power of voice with compression is about 13dB lower, or about 200mW per foot.

Explains why it has worked ok, doesn't it!

If you dig into the numbers, about 25%+ of your transmit power is lost in the line losses, which is a compromise you acceptaed for the lighter weight line you needed.

Many years ago, 1950s, there was a very active 10 meter ham in Danvers, Massachusetts, during the period of Class A, B and C licenses. He was an arthritic quadriplegic. He was wheel chair bound, lived alone, and required visiting help to get into and out of bed and have his meals prepared and served.

He had a Class C [Conditional] license. He learned to copy 'read' CW in his head although he did not have the ability to send. I don't think he would consider a lawsuit appropriate.

Some of the OTs on this list may have worked him. W1JFS, Les MacCrakin. God Rest His Soul.

Having hired many engineers in my lifetime I can state that good engineers meet several criteria:

o meet the technical requirements established by your customer,

o meet the schedule established by your customer,

o meet the costs established by your customer.

Economics is only 1/3 of good engineering talent.

Well I described a number of alternatives to learning and he persists in saying he cannot learn code. Now I have not insulted him that I know of (although it's difficult to predict what one might take as an insult). However, if someone truly is incapable of learning code, then they are unable to learn to understand the spoken word and to speak. The fact that he can speak and understand the spoken word means he can learn code at the basic level of 5wpm. He is his own biggest enemy.

A completely deaf person can speak and read lips but he/she
still cannot even hear Morse code. What you need to understand
is that something that seems normal to you is missing in some
people. If an amateur radio license required dunking a basket-
ball, could you do it? As one who can dunk a basketball, I can
tell you all you need is enough will and effort and you can do it.

My point exactly. Recruiting foreign eng talent is driven primarily
by economic reasons. The oft repeated lament by corporate flacks and
politicians that we lack sufficient talent at home is a damn lie.

With deaf people use can use a light or a subwoofer for them to copy code. I don't want to stereotype deaf people, but I have found many of them to be hooked on entitlements and expect unreasonable accommodations. I have a relative that refuses to wear a hearing aid, and then gets angry when there are communication problems. This person is physically able to work; yet sits around on my tax dollars playing the feel sorry for me card.

Deaf persons have succussfully completed the code portion of the testing at all levels of speed. Some use a vibrator attached to their wrist. Others us a light. As mentioned elsewhere "never say never".

So now you are saying you were talking about arcs in connectors?
Talk about diversions!

You SPECIFICALLY proposed the noise came from millions of dust
particles hitting the antenna each second. RF noise generated directly
by charged particles hitting the antenna. No arcs, no corona according
to YOU. Not me!

> I modified my dipole into a folded dipole. The arcing ceased
> and I could then hear signals. I estimate the signal to noise
> ratio was not zero any more. Would you disagree?

Well, I would agree you have a VERY screwed up system to start with if
you had a big antenna without a leak resistance that offered a high
resistance or reactance at radio frequencies.

I've said all from the very start no one should be so careless as to
float the antenna.

> I really question the IQ of anyone who asserts that eliminating
> arcing in a system doesn't reduce the noise. I assume you are
> not a member of MENSA. :-)

Nice tactic. Attack the other guy while totally changing what you
originally claimed.
Of course anyone can read back and see you were the one who claimed the
noise was from particles hitting the antenna.

Anyway, I'm glad you realized your folded dipole nonsense about the dc
loop stopping p-static from particle noise as they hit the antenna was
just that, and now you realize it is charge differences and arcing and
forms of arcing that causes the problems.

Pretty soon you will realize the largest charge difference is from the
air and things in the air around the antenna and earth that causes the
problem, and that grounding the antenna doesn't reduce that problem.

There's hope for you yet!

> when a t-storm comes in the area.

Ken,

The connector itself is dimensioned almost the same as a type N
connector.

The limiting factor assuming a good quality properly installed BNC
connector is the cable, not the connector.

If you use a good high temperature cable in a dry room-temperature
environment 500 watts extended time with carrier is a reasonable amount
of power. That power increases quite a bit for shorter duty cycles.

We used BNC's on a 3500 watt 30 uS RF pulse generator at 40.68MHz, and
I've used them with CW and SSB with good Teflon cables at 1500 watts on
30 MHz as quick disconnects.

If you carefully exam the BNC you will see it is nearly identical to a
type N in air gap to ground and pin diameter and penetration depth. The
real problem is the cable, not the connector.

> So now you are saying you were talking about arcs in connectors?

I have been very careful from the very beginning of this
thread to specify that the problem I was trying to solve
was arcing at the coax connector. You said a folded dipole
cannot solve that problem. You were wrong.

> You SPECIFICALLY proposed the noise came from millions of dust
> particles hitting the antenna each second. RF noise generated directly
> by charged particles hitting the antenna. No arcs, no corona according
> to YOU. Not me!

Sorry, I even said the arcing scorched my carpet when the coax
connector was disconnected. Anyone who wants to check the history
of this thread can verify that. Your assertion that a folded dipole
wouldn't change the noise level was 100% false.

> Nice tactic. Attack the other guy while totally changing what you
> originally claimed.

If you can prove that I changed what I originally claimed, I
will write you a check for $1000. From the very beginning of
this argument, my problem was arcing. You asserted that eliminating
arcing didn't change the noise level. You were wrong. Anyone who
wants to can go back and verify those facts can do so.

> Of course anyone can read back and see you were the one who claimed the
> noise was from particles hitting the antenna.

Yes, it was, and it caused arcing which I needed to eliminate.
The folded dipole eliminated the problem contrary to what you
asserted.

> ... and that grounding the antenna doesn't reduce that problem.

Grounding the antenna eliminated the arcing which was my problem.
Sorry about that, Tom, but your ignorance has been exposed. Seems
you need a tutorial on how a DC arc can convert energy to RF
noise.

If I don my knee braces, I still can. Can you?

The point is that some things are possible for each
individual and other things are impossible. Anybody
who can't dunk a basketball or pass a MENSA exam should
know how a person feels when they can't learn Morse code.
I personally think it would improve the ARS to only allow
MENSA engineers to be a member. How does that make you feel?

One of the brightest engineers I know, who has a commercial
FCC license and was the engineer at an AM broadcast station,
couldn't get past 5wpm so he was condemned to Tech class for
30 years. He knows more about radio than any ten other hams.

Not a correct analogy. For starters, completely deaf people have learned the Morse code. Flashing lights and pulse pads have served their needs. Just as they have learned to speak and read lips, they can learn alternative methods of using code.

The 5wpm level is more equivalent to dunking a basketball in a basket that is just above head height rather than regulation professional height. Under those conditions, anyone can dunk a basketball.

The biggest reasons people "cannot" learn code are very simple.

1. They don't really want to and so subconsciously resist.
2. They have been subjected to poor training methods.
3. No one's ever taught them correct practice methods.
4. They have developed unrealistic expectations of the level of effort required.
5. Due to bad experiences resulting from the above items, they've convinced themselves they can't learn and so create a self-fulfilling prophecy.

Every problem that Sal has described has afflicted almost every student of Morse code (except perhaps for the very rare code geniuses). Forgetting letters right after learning them? Been there, done that. Confusing letters? Been there, done that. I've had to bow out of QSOs because my brain freezes up and refuses to keep copying.

It took me 3 months of daily practice of an hour or more every day to get to 5wpm. That's over 90 hours. The average person only needs about 30 hours. I experienced every problem that "Sal" has mentioned. I eventually went on to master the 20wpm. That took 9 months of the same intensive daily practice, over 270 hours. Fortunately I wasn't hobbled by the expectation of learning it in a few weeks. Luckily no one had ever told me I could learn it in a few days or weeks. So I just kept at it for however long it took.

True enough but that accommodation has been accepted for a very long time.
The regulations also said that they must be by hand. A sending test hasn't
been used in decades except as an accommodation for people with hearing
problems, etc. The FCC itself had stopped administering a sending test
before they turned the testing over to the amateur community.

But the letter of the law says they must receive Morse code
by ear. Anything else is a violation of that law. It's
like qualifying to be a life guard by doing a broad jump.

try 5 years at 40minute per day, I frankly prefer not to do the math to
come up with the nuber of hours

and still NO sucess

now of course if you respond to me at all you blame my metohod or my
unkonwn to you teachers etc.

everything to avoid the central issue why is Code knowledge more
important than the rest of Ham radio combined

that is the issue of course I say more important since their question
in pools about cw that tip it from equal to the rest to more important

Well the accommodation has been used and accepted for a very long time. The regs also say send by hand but no one has administered a sending test in decades except as an accommodation to individuals with difficulty in receiving.

Your life guard analogy doesn't hold up either. Instead it would be like allowing the life guard to use a row boat instead of swimming out to the victim.

You have just admitted that the Morse code test has been
irreversibly compromised already. A deaf person holding an
HF ham license cannot hear an SOS so the entire purpose of
forcing him to learn Morse code is bogus. He is going to
be using a digital mode, not sitting there with his hand
on the speaker waiting to feel an SOS from a sinking ship
that doesn't even have CW capability anymore.

Believe me, this guy shed tears when he couldn't get past
10 wpm. He has a physical mental tick every few seconds, akin
to epilepsy, that causes him to lose time. He cannot speak
one minute of continuous speech much less receive one minute
of continuous Morse code. When he speaks, some of the time
is silence while his brain is out to lunch. But when he
does speak it is worth ten times the average person's
utterances. He is an engineering genius.

That's what they are replacing the CW test with, the slam dunk. Now all
those hams with their Hover Rounds will have to give up their tickets.

Yea, I stated a thread about that titled ham operators...why must they ruin
RRCB?

Eric Oyen was the only ht ham to tell me how wrong I was. Oh well.

(sock puppet hams generally post gay shit below here.

I have rebuilt a W2AU balun for much the same reasons.

Like the referenced article, I removed the dual use of the electrical connection for support of the dipole wires.

An addition, I changed the coax connector for an N-type for a water resistant cable connection.

Having said that, I don't use it much, it is a "voltage balun" and most of my applications are better suited to a "current balun".

Owen

Why not get rid of the code? Really, why not make the written exam easier? Just make exams covers enough to make sure some idiot doesn't kill themselves or some body else.

Have only one class of license called "Amateur Radio License", with full access to all bands. No matter what class a person holds now it would be renewed as only "Amateur Radio License". Novices would be grandfathered in.You couldn't get any worse class of ham than we do with the 20wpm wonders.

The model has to include a wideband, low-loss step-down transformer.
Which may or may not be a balun. Eg., a 300-ohm down to 50-ohm
transformer.

As Roy implies, such transformers are difficult to construct in
practice because performance depends on source and load impedances.
But very easy to incorporate in a mathematical model. Just divide
line impedance R+jX by 6. Consequently, the model will not accurately
predict what will happen in the real world unless terminating
impedances are fully taken into account.

A Spice simulation program is needed rather than an Eznec type.

Reg.

I don't think you insulted me -- it was whoever said I don't deserve a
license.

However, I do think it's a bit of a stretch to say that I can learn code
just because I can speak and understand words. You should see what my raw
typing looks like before I go back and fix it prior to hitting send (or
should I say "sned," which was what I typed the first time -- typically four
or five of those per line.) It's pretty bad.

I'm thinking of trying to learn the dits and dahs as strings of written dots
and dashes on paper. According to everything I've been told or exposed to,
that is not recommended. All the training says the goal is to perceive each
letter as a consolidated unit of sounds without any intermediate translation
steps. Well, since I'm positive that isn't working, particularly for
characters of four or more elements ... maybe a graphical alternative is in
order.

You have extracted something from my post that was never there. No one has ever said that the purpose of hams knowing code was to hear a ship sending an SOS.

In addition, he might have a light rigged for cw, which he could see as he moved about the room.

Digital modes fail on a regular basis due to static, auroras, etc. It's a good idea to have a non-voice, non-computer alternative.

Since the late 80's, he could have gotten a medical waiver for the speeds higher than 5wpm. His case proves my point though. i.e. He did learn the spoken language despite his problem. He did learn the 5wpm despite his problem. His problem manifests itself in dealing fluently with the spoken language and also manifests itself in dealing with higher code speeds.

A problem that would affect the ability to learn code affects the ability to deal with the aural/spoken language.

1. Incorrect training methods. These abound. There are more bad ones than good ones around.
2. Incorrect practice methods. Many teachers and students don't really know how it should be practiced. They just muddle along. Among other things, that means daily practice not just getting together with a teacher once a week. It also means breaking the daily practice session into 15 minute increments so the brain doesn't fatigue.
3. Unrealistic expectations is quite possibly the biggest one. People think they should be able to learn it in a few days or a couple of weeks. It takes the average person 30 hours to get to 5wpm. At an hour per day, that's one month. A more comfortable pace is 1/2 hour per day for two months. (It took me closer to 90 hours.)
4. Disapppointment created by the above issues causing a person to believe they can't do it thus creating a self-fulfilling prophecy.
5. Not wanting to do it so they end up fighting themselves subconsciously.
6. Negative reinforcement by those who tell them that code testing should be eliminated because it is "useless". Anyone who's seen HF trashed by static or aurora should know better.

It was part of a rebuttal to someone who said that requiring 5wpm code was
as reasonable as having to be able to dunk a basketball.

Typing and reading are visually based. So it makes sense that those are a problem. But do you have difficulty saying words or hearing them? Just because the typing is a problem, doesn't mean that the aural/spoken is a problem. Reading/writing is a different activity than hearing/speaking and uses different parts of the brain. While I can't imagine a graphical method working for a dyslexic since it's visual, who can say for sure.

By the way, I still have problems with longer characters now and then or combinations of certain characters. I had an awful time trying to copy a call sign in a contest that began with SH5 (3 dots, 4 dots, 5 dots).

Recently I can across a "music" track that is about 5 minutes long that
teaches Morse by the sound of the characters.

If you would find this helpful I may be able to get a copy of it and
place it on an ftp server for you.

Regards

David

Outsourcing started way back in the 70's. It has only been in the last
decade that anyone in the media and public paid any attention to it.
When layoffs became common place after the dotcom bust then the public
finally realized that the barn door was open and nearly half the cows
are gone. A bit to late.

Okay, Tom. I'll accept that you have personal experimental results for
your statements. Not many do.

I'm not sure that anyone here believes Cecil just because he is Cecil.
I don't. Some times I see him posting his way into some very deep holes...

I am corrected. You both determine everything experimentally and enjoy
busting on Cecil. I assumed an "And" situation, while it was actually an
"OR" situation.. 8^)

Please stop pretending that you didn't know I was talking
about arcing.

Going from a dipole to a folded dipole eliminated my arcing
problem.

> really is?

Well, suppose you have a #18 ga stranded wire composed of 7 strands of #26. One strand is sticking up all by itself. The end of the strand (if cut off squarely) is about 0.0013 cm^2. So a current flow of 0.13 uA from the end of this strand is 100 uA/cm^2.

And, the situation is exacerbated by wire with smaller strands and with strands more pointed than by being squarely cut off.

John

We can suppose all sorts of conditions to obtain corona.
There's absolutely no argument about that. The argument
is whether corona occurs 100% of the time on any and all
antennas with charged particle static. If corona occurs
only 99.9% of the time, the corona gang loses the argument.

The argument is whether corona *always* accompanies charged
particle noise. That's an exclusive assertion that there
exists no cases where corona doesn't accompany charged
particle noise.

I fully agree that corona *often* accompanies charged particle
noise but that's an inclusive assertion.

If enough particles hit the antenna to just
barely hear the noise on a receiver, the corona crowd says
that corona caused the noise. I would like to see some proof
for such a statement so far out of mainstream physics.

Can we suppose a condition where corona won't happen?
How about a #14 solid wire with rounded ends? Do you think
it could build up enough charged particle noise to be heard
in a receiver without the existence of corona?

Well, W8JI said going from a dipole to a folded dipole
doesn't change the noise level. Not only did it eliminate
arcing but it probably eliminated any trace of corona.

"hungry" and "homeless" people are there by their own choice or by choices they have made in their past. The welfare system doesn't work, otherwise there wouldn't be 5 1/2 MILLION people dependant on it.

Yes..... I have a problem with the system when 28% of my *net* profits get paid to the feds to support lazy dead beats, and another 4% goes to the state for the same.

I am retired Military, I served my country for 22 years, My father was born in this country by the grace of god, and couldn't speek the language until he was in grade school. When I retired from the miltary, I started my company and have worked my ass off for 10 years to get to where I am now, finally starting to make a comfortable living.

There are too many jobs out there for folks to be unemployed, homeless, or hungry. Those that are unemployable are those who by their own choice, can't seem to show up to work, let alone on time...those who can't seem to show up for work sober and not hung over, and those who can't seem to be able to pass a drug screening. If I could find somebody that *COULD* meet those minimum standards and had a little common sense and a desire to learn, I would hire them in a heartbeat, and they will earn good money.

They have made their choices.... I for one am damned tired of having to foot the bill for their irresponsibility, lazyness, and feigned ignorance(you can't be ignorant and be able to sponge off the system)

not clear who you are addresing

but this method get tried on most dyslexics and rarely works

why> gald I asked becuase most dyslexcs ebd up doing the easier for us
task on meoris 5 minutes of letter (learn though correcting our efforts
at the end) rather managing to sort of the tone

In Dyslexia, ones is up against one own brain and the methods one has
learned to work around the misfiring nurons most dyslexic learn very
effectve methods of dealing with, and the btter the devolped method is
the harder it is to defeat. Code testing tries to channel one down a
path of limited choices

???

(Reagan's Welfare Queen was a myth, you know.)

When a company moves offshore they do not reduce prices to the end
users. They increase their profits. Most big companies don't even
pay income taxes because they are legally running out of a drawer in
some Carribean island.

Eventually the middle class will be gone due to outsourcing. That
will be the end of the USA.

you are probably correct. linguistics is mainly concerned with spoken language, not written. in some languages like English, you'll note that people kind of speak the words out in their brain. other languages like Mandarin seem to be converted directly from characters into ideas.

ok, what burns me up is people claiming they can't learn code. there are languages that are tonal, configurational, have bizarre sounds, that put the object before the subject, that have thousands of characters. 99% of the planet learns their native language!

code is NOT that different than a language. if you must, you can interpret it as tones, and simply write out the tones on a piece of paper and decode them.

same here!

i have trouble with high speed B, 6, 1, J. however, you can create a
practice regimen that focuses on these.

a trick for contests might be using a spectrograph or MFJ viewer. good
luck.

good practice is beacons e.g. 10 meters. they are terse text, contain
slashes, and 5s since i hear Texas ones.

you sort of have to "decode" what the beacon is talking about.

that's what i see. he says something controversial, gets challenged, and
then scrambles for references. the problem is that many of the references
do not directly confirm what he's saying, and a bit of calculation is
required.

i did some googling, and certainly there are others with Cecil's position.

i hate to play devil's advocate, but i can read CW with spectral analysis
software. several of us on the very low bands are doing that.

yes, the chances of some deaf guy "hearing" an SOS is pretty slim.

it's sad that people get alienated from hobbies. it's also a fact of life. i downloaded some composition software, and it turned out i SUCK at making digital music.

i can play the second movement of Moonlight Sonata, but that's about it.

i remember this girl in chemistry class. she studied 5 hours for a test. i studied 10 minutes. my score was 30 points higher than hers. i wasn't necessarily smarter than her, i just knew how to study, and same thing with CW.

i learned Morse Code at age 15. i got up to 25 WPM, perfect copy. i made QSOs, did a few contests, and quit for 9 years.

i now copy at 18 WPM, which makes me think i learned it like it was a language.

some suggestions. use Farnsworth, copying characters at 18 WPM is less annoying.

make QSOs! would you learn a language by using audio CDs, or would you talk to native speakers?

find out what the format of the test QSO is!

i didn't study much for my novice code test. i had no decent tapes, and i had to borrow my dad's computer to use software. computers back then were $2000 and no kid had one.

so anyway, i use Supermorse as recommended by my club. i get to the test, realize my code sucks, and luck out because they do a Supermorse QSO.

it's easy in today's world: free practice MP3s and $50 computers.

Rather than rationalize and walk through disagreements step-by-step
Cecil prefers to distort and bully.

His posting ratio averages 3.3:1, and sometimes reaches over 6:1.

if you are contesting or DXing, CW rules.

HF phone contests will drive you insane, esp if you want to win an award.
even 10 meter phone was wall to wall stations from 28.300 to 29.000. i had
phased Yagis, and had to go way high, or end up stomping on someone.

if you want to run DX, good luck with 100 watts on SSB.

That may be what someone told you, but it was not the reason. The reason was that it was part of an overall "radio education" and it was one of the fundamentals of radio even in the 1950s.

Back when I was young and interested I lost my desire to learn code when I
started monitoring the ham bands. It all seemed too formal, and then like it
is now, you have a large segment that think you are trash if you don't have
the highest obtainable license. Even this thread proves it. You have a large
contingent hell bent on having CW testing with any class, even though I
never plan to use CW. I could get my Tech ticket, but then all I'm going to
hear is that I'm a no-code tech. I rather be a CBer as we have no cast
system.

You're a tough guy.

During a more civilised time a company went into business to provide
jobs and make profits and to be part of a community. Nowadays
corporations are extranational, have no local ties and just milk
markets dry and move on.

Corporations pay way less than half th cost of running governments,
even though they are the major beneficieries of what governments
provide. This is because we let them write their own rules.

> in a receiver without the existence of corona?

I applied simple arithmetic to show that 100 uA/cm^2 is almost meaningless because there are conditions much more favorable to the generation of corona to consider. If I am wrong, please correct me.

Frankly, I think you should try to make up a condition that refutes your own suppositions and see if it flys. If it does, then think of something else. I do that all the time. Sometimes I learn, and sometimes I don't. I try to temper my investigations by asking questions.

Why #14 with rounded ends? Because it supports your position? Why not suppose smaller wire and sharper points? Make some calculations for us to review. Use the worst case against yourself, then show why it cannot be so.

Frankly, Cecil, I have been somewhat of a follower of yours for some time. You have some thought-provoking ideas and comments, but I am beginning to believe that your entire purpose is to argue. I wish it wasn't so.

First not every homeless and hungry person is there by their own
choice. There are those that the system chrushes and grinds into
pieces just for beign at the wrong place at the wrong time. The
welfare system does work. Yes decision and actions in all our past
make differences. Yes some want to live the way they do. Somewhat out
on the fringe of society.

Corporations do pay taxes. The expense of taxes is often passed on
where feasable. Often these are in higher selling prices. Often taxes
do intrude on profits. When they do, there are steps taken to regain
that profit. Outsourcing is a means of regaining profit. Cutting
benefits and maintaining salaries is another. There are other means
also.

From Websters:
"rationalize - 1. to ascribe (one's acts, opinions, etc.)
to causes that superficially seem reasonable and valid but
that actually are unrelated to the true, possibly unconscious
and often less creditable or agreeable causes."

I agree that describes exactly what you do here on this
newsgroup but why do you think rationalizing is a good thing?

My supposition is that it is possible for charged particle noise
to exist without corona. That inclusive supposition cannot be
refuted by one condition. That supposition can only be refuted
by all conditions which is not possible to implement in reality.

My type of supposition: Not all cars are white.

This cannot be disproved by only one example.

The other sides supposition is that charged particle noise is
always accompanied by corona. All it takes is one example to
refute that exclusive assertion.

Their type of supposition: All cars are white.

This can be disproved by only one example.

> Why #14 with rounded ends? Because it supports your position? Why not
> suppose smaller wire and sharper points?

Seems you misunderstand. I'm not saying corona never occurs.
I'm saying it is possible for charged particle
noise to exist without corona occurring. Do you understand the
difference between an exclusive statement and an inclusive
statement? It's the other side making the exclusive assertions.
All I have to do is present one example where charged particle
noise exists without corona. That case may be a #14 wire with
rounded ends.

I have made no exclusive statements. If there is corona in
99.9% of the cases, the other side still loses the argument.
It is the opposition that has made the exclusive statement
that charged particle noise is *always* accompanied by corona.

My supposition is that charged particle noise is NOT always
accompanied by corona.

> This cannot be disproved by only one example.

i think this is modal logic. "all cars are white" is a statement about the whole set. thus the whiteness of each element must be verified.

we get into semantics. what is "white". what is "car".

sometimes the situation gets complex. we can prove that 100% of the zeroes fall up on the critical line, but this does not rule out a counterexample. i guess my main point is we need to define "clear weather charged particle noise".

I don't know much about spark. Was the length of the spark
controllable such that dots and dashes could be differentiated?

It's what happens when the wind blows in the Arizona
desert when the humidity is low and there's not a
cloud in the state. There are hundreds of reports
on the web of such a phenomenon. Example:

click short pause clack = dit
click long pause clack = dah

i think it would be hard to decode vs listening to a modern receiver.

i believe spark gap would be useless in a rescue situation.

i researched ULF antennas and came up with this:

1. triboelectric noise due to movement
2. static on long wires due to lightning

on microwave, you'll get tropospheric scintillation noise.

you are talking HF, so i dunno much.

I said:
w...@akorn.net wrote:
> The "dc path eliminates noise" and the "noise comes from each particle
> hitting the antenna and a dc path reduces it" are nearly as far
> fetched.

I already explained that to you, Tom. Perhaps you missed it.
In the following diagrams, CH is the charge transferred to
the antenna by a charged particle or any other means.

Given a non-folded dipole, any equalizing of the charge between
the two identical dipole elements must flow through the link
where the noise is picked up by the receiver.

```
-------CH------+ +---------------
| |
/ /
| |
Link to
receiver
```

Turning the non-folded dipole into a folded dipole provides
a *local DC path* between the two elements. Most of the
noise will follow that DC path between elements instead of
traveling down the transmission line, through the link, and
back up the transmission line. Hint: Ohm's law.

```
DC path between elements
+------------------------------+
+-------CH-----+ +--------------+
| |
/ /
| |
Link to
Receiver
```

You avoided replying to this last time. One wonders why.
Please explain why you think the charge on the folded dipole
would not take the DC path of least resistance.
--
73, Cecil http://www.qsl.net/w5dxp

>>>>end of quoted text.

The above nonsense is what gets Cecil in trouble.

1.) First he clearly stated he thought the noise was from each individual charged particle of dust striking the antenna millions of times a secon making a noise at radio frequencies.

2.) Then he wrongly assumed "shorting the antenna for dc" would also "short the noise". '

He apparently missed the fact HE (Cecil) claimed the noise was radio frequency noise caused by each particle hitting the antenna. If it was such, shorting the antenna for dc would only make the noise worse.

Now it seems he is changing his tune, saying it is arcing in the coax that is a concern.

Cecil paints himself into a corner with silly statements. Then he tries to cover it up by saying he never actually said what he said.

But at least now we are in agreement. The noise is caused either by arcs or corona, not by particle discharges into the antenna as they connect.
That's all that is really important.

....and it happens here in humid Georgia, and in dry Georgia, and in
Ohio in summer and winter. There doesn't need to be a particle in
sight.

I can go outside and float the feeder of my long 160M dipole that is
300 feet high. The whack will knock you right on your rump. But that
charge is actually pulling the antenna CLOSER to the potential of the
air around the antenna. When I ground that antenna so the antenna moves
to earth potential, the corna from that antenna actually gets
worse....not better.

The reason is pretty simple. The earth is a big charge sink, and is
really at considerably different potential than the air at 300 feet
even on a clear calm day. A little wind helps quite a bit, pushing
charged air past the antenna and increasing the charge rate.

What most people miss is that it is the difference in potential between
earth (or lower heights) and the air around the antenna that causes the
leakage currents. The wind simply increases the problem.

Here is where Cecil claimed the noise was from individual particles
hitting the antenna:

From: Cecil Moore - view profile

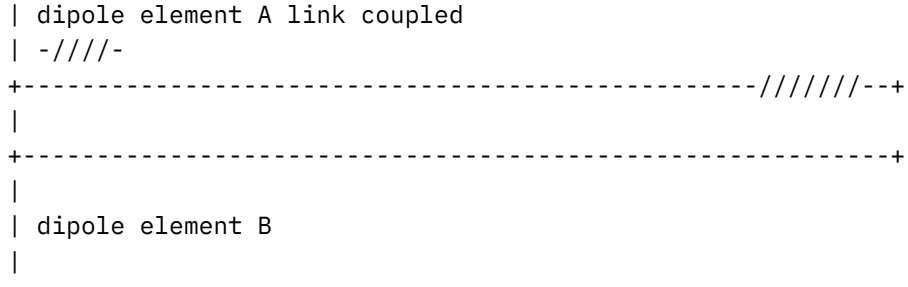
Groups: rec.radio.amateur.antenna
w...@akorn.net wrote:
> People actually seem to think the little particles voving through the
> air charge the antenna to a different potential than the air around the
> antenna, and that a "dc" path to earth or "dc" path around an element
> somehow magically stops RF noise.

Let's say we have the following bare-wire dipole system
link coupled to the receiver (in fixed font).



Let's assume one highly charged particle hits dipole element
A and transfers half of its charge. Element A will then have
an excess charge one half of which will migrate through the
link while equalizing the charge between element A and element
B. That charge migration/equalization no doubt results in an
RF noise pulse.

This experiment can easily be performed by anyone.
Rub one's leather soles on a wool carpet, touch one side of
the dipole, and listen for noise in the receiver. Guaranteed,
it will be there.

Now multiply the above by millions of charged particles
randomly encountering the bare-wire dipole. The charge on
each side of the dipole will never be exactly equal. Thus,
continuous broad-band noise will be continuously transferred
through the link as long as the particles are transferring
charge to the antenna. That's what some hams are hearing
during dry-air dust and snow conditions. Some have even reported
being able to hear individual particle collisions from large

snowflakes.
--
73, Cecil http://www.qsl.net/w5dxp

>>

Cecil claimed P-static was broadband noise from each particle hitting the antenna. Notice, unlike Cecil, I don't lift things from context to change the meaning. His full unedited statement is above, and it shows what he intended to say.

He made several clear posts like that, but at least now he seems to be coming around and understanding it is arcing and corona noise.

particle rubs against aluminum antenna and creates triboelectric charge.

a different particle transfers charge to the conductor.

wind movement causes triboelectric noise.

i'm not sure if all 3 of these are the same thing.

> 73 Tom

Umm, no, two different things.

If it were charge building somewhere and discharging it wouldn't have the characteristics it does, which is random, continuous, of extremely short duration, and at a very high rate.

When it gets bad, it is quite visible as very random "snow" on TV channels 2 through 4 on an otherwise perfect picture.

The snow is spots of extremely short duration.

Arcing (my neighbor has an arc welder so I have something to compare it to) shows up as lines. When watching TV while he is welding it is very obvious from the visual "noise" when he trying to start an arc on some rusty thing versus an established arc from the length of the visual "noise".

This particular effect ONLY happens during low humidity on very windy days.

The intensity of the snow changes very little with wind speed, the duration not at all, but the rate changes drastically.

I took all the electromagnetic courses to get my BSEE and I'm a pilot, so yes, I know about corona.

Obviously, I didn't say each particle strikes the antenna
millions of times a second. What I said was that although
others had reported being able to hear each individual
collision, I had never been able to do that. So your statement
is false.

> 2.) Then he wrongly assumed "shorting the antenna for dc" would also
> "short the noise". '

You are mixing apples and oranges. This was in the context of
eliminating the arcing of my coax connector laying on the rug.
Sure enough, shorting the antenna for DC eliminated the arcing
thus eliminating the noise. Your statement is deliberately
misleading.

For the record, when the wind was blowing charged dust particles
across my bare wire antenna under a clear sky, the S-meter noise
increased as the wind speed increased and decreased as the wind
speed decreased.

> He apparently missed the fact HE (Cecil) claimed the noise was radio
> frequency noise caused by each particle hitting the antenna. If it was
> such, shorting the antenna for dc would only make the noise worse.

No, I didn't say that. I specifically said that it was NOT me
who said they could correlate noise to each specific particle.
Is the only way you can win the argument is to falsify what I
have said?

> Now it seems he is changing his tune, saying it is arcing in the coax
> that is a concern.

No, you are the one who is mixing up the two different subjects.
One was an arcing problem that I needed to solve. The other is
the measures that can be taken to make an antenna less noisy.
Please stop the deliberate mixing of these two subjects. I am
willing to rationally discuss either one separately.

> Cecil paints himself into a corner with silly statements. Then he tries
> to cover it up by saying he never actually said what he said.

As you are doing, I could cut and paste your postings to make you
seem ignorant and insane. But only an unethical person does that.

> But at least now we are in agreement. The noise is caused either by
> arcs or corona, not by particle discharges into the antenna as they
> connect.

No we are NOT in agreement. In the absence of arcing or corona,
charged particle noise exists and has been experienced by many
people. A web search for "precipitation static" will yield any
number of references, including amateur radio references.

We are talking about antennas that have virtually no charge when
the wind is not blowing and acquire charge when the wind blows
charged particles across the antenna.

It is something that you have apparently never seen are are
therefore completely ignorant of.

w8ji@akorn.net wrote:
> Here is where Cecil claimed the noise was from individual particles
> hitting the antenna:

Sorry, Tom, you are mistaken. Read it again. It is true that
each individual particle that touches the antenna transfers
some charge but the following was *purely hypothetical*. I have
NEVER said I could hear the noise from an individual particle.
"Let's assume" is what one utters just before a hypothetical
exercise in logic. It is obviously hypothetical because exactly
1/2 of the charge is assumed to be transferred.

> W5DXP said:
>> Let's assume one highly charged particle hits dipole element
>> A and transfers half of its charge.

This is a hypothetical experimental charged particle as one
would get by rubbing amber on wool and touching it to the
antenna.

w8ji@akorn.net wrote:
> Cecil claimed P-static was broadband noise from each particle hitting
> the antenna.

That's a false statement. When I said *assume* one highly charged
particle, it was a purely hypothetical particle. CP-static is
a cumulative effect. I personally have never heard one particle
hitting an antenna although others have reported that they have
heard it. I have never said that one particle hitting the antenna
could be heard in the receiver.

> Notice, unlike Cecil, I don't lift things from context to
> change the meaning. His full unedited statement is above, and it shows
> what he intended to say.

You are attempting to change the meaning at the present, Tom.
That was a hypothetical highly charged particle, Tom, not one
that is likely to exist in the real world. I have previously
said that I could NOT hear the individual particles. My hypothetical
highly charged particle was like a piece of amber that had been
rubbed against wool and then touched to the antenna. I suspect
that one could hear that event in the receiver.

> He made several clear posts like that, but at least now he seems to be
> coming around and understanding it is arcing and corona noise.

Please stop the mind fornication. Such is highly unethical
but unfortunately standard practice for you for years now.

Sometimes noise is caused by arcing. Sometimes noise is caused
by corona. Sometimes noise is caused by charged particles in
the absence of arcing and corona. I am NOT coming around and
I do NOT seem to be coming around. Please stop misrepresenting
what I have said. It doesn't make you look any less ignorant
and it confuses the readers.

If you want to proceed with a rational argument, I can explain
and defend everything I have said and I am NOT coming around
to your strange concepts.

So one can see the individual charged particles even if
one cannot hear the individual charged particles. That
makes a lot of sense. I wish I had thought to hook my
antenna up to my TV while the charged particle problem
was occurring.

I have problems with most characters of four or more elements length.
Exceptions are <period> and <Q>, for some reason. As I have said here,
after hearing dit-dah-dah-dit identified, whatever it is, I cannot
subsequently hear it and know what it is. I think my own first name
initial, <J> is some combination of three-and-one or one-and-three, but I
can't remember it. Oh yeah -- I know <V> because the dit-dit-dit-dah sounds
like the 1812 overture.

I dial a telephone with two fingers -- one pushing the buttons and one
holding my place in the phone book, since I have to go back and look at the
number repeatedly. Yes, I do memorize phone numbers, but I may invert the
digits when I try to dial them. This is a royal pain in the ass.

When I joined the Navy in 1962, one of our tests was for clerical skill,
which involved inspecting columns of numbers and calling the entries on each
line either ALIKE or DIFFERENT. I scored a 35, lower than anybody I ever
met. I wanted to be a Yeoman (clerical duties). Instead, they sent me to
ET school and I've never looked back.

I'll read any responses, but I think I'm pretty well talked out on this one.

My homebrew 3 foot dia Magloop works very well vertically mounted 3 foot off the ground but i`m wondering if maybe it could do a little better in the low angle radiation department ....i seem to hear stations within 1000miles consistently strongest.....VKs and stateside etc much lower !!!.....

The loop is mounted on a rotator above a groundmat buried about 6 inches beneath the lawn and consists of 30 radials each about 30 foot long and the loop is mounted in the centre, is that ok, or should i work the loop higher than 3 feet above the mat, or remove the ground mat and work just with medium loam soil underneath instead??........

Thanks to Cecil and others for help and advice in building the loop, it tunes 40 thro` 15 meters......

Lee......G6ZSG.....

With a low height "vertically polarized" loop the ground would never
hurt the antenna and always help it to some extent. The only exception
might be if the soil is so very poor it looks nearly invisible, or so
good it looks perfect.

I would not remove the ground mat, although 6 inches is pretty deep!

A small loop is a very inefficient radiator unless you do everything
perfectly, and if perfectly done it has mediocre efficiency.

So how did you build the loop?

Lee,
Signals within 1000 miles come through strongest because they are nearer to you.

Also, with an antenna height of only 3 feet, low-angle reception and radiation suffers from being screened by buildings and other obstructions in the vicinity of the antenna.

At low heights there is a considerable power loss induced in the soil under the antenna. Your radial system is of little use. Only a large metal sheet placed on the soil surface would be effective.

Your buried radial system is an overkill. If it was removed you would probably notice no difference in performance. But the radials will perform an excellent service if you should later wish to erect a vertical antenna above them.

An increase in height will result in better low-angle DX. Increasing height to only to 8 or 10 feet should produce a noticeable improvement. And loss in the ground will be negligible.

To get it above ALL low-angle obstructions, fix it to your house chimney. ;o)

Reg, G4FGQ.

It is my custom to trim out the part of postings with which I
agree and respond to the part with which I disagree. I believe
that is in accordance with the newsgroup guidelines. I do not,
as you do, cut and paste to completely change the meaning of
what was previously posted so you can attack a straw man of
your own creation.

Your latest posting, where you take my mental exercise example
of a hypothetical antenna with a hypothetical highly charged
particle hitting it to try to prove that I said each real world
particle causes noise that can be heard in a receiver is really,
really lame.

> That is why Roy and others have you in a "Cecil filter".

Roy ploinked me because I said an antenna is a distributed network.
I thought he had previously said an antenna was a lumped circuit.
Instead of telling me that's not what he meant and giving me a chance
to apologize, he ploinked me.

When you are willing to rationally discuss those hypothetical
examples I have posted, let me know.

i used radials with my monopoles, but not my vertical dipoles. i have never used a Magloop.

i suspect getting an antenna off the ground helps. the trees and buildings are out of the way. does it lower the elevation angle? does it change ground loss?

just as an example, i tried a 10 meter vertical at 100 feet. it compared favorably with a tribander on some paths! conventional wisdom is that a beam smokes a vertical.

Message-ID: <129qn4gq8iod1f@corp.supernews.com>
Source record: 57203

Dear Jim Pennino WB6DKH:

Well said, and yet here we are over 100 messages latter (even with a
Cecil filter) with strange contentions still going on. It has become
apparent that this is a religious debate and it is time for additional
filtering.

To supplement my message of June 7, 2006:
One should provide continuity to earth from as many elevated conductors
as possible. It is sometimes difficult to do this with guy wires that are
"broken up" with insulators.
Location is an important factor with respect to which local,
non-man-made noise sources dominate. In Toledo, Ohio and Georgia it might
be one thing and in the Arizona desert quite a different thing.
Time and local weather is also an important factor. Lighting discharges
off of, or towards, an antenna will dominate everything else.
Having spent the last 73% of my life in an academic setting involving
science and engineering where orthodoxy applies only (temporarily) to
verified physical laws, I now understand why wars are fought over which end
of the egg is cracked first. It has rounded out my education.

As Roy has pointed out: it important to observe to the readers who are
not participating that they should filter what they read with care.

Thank you Jim for interjecting your experience.

73 Mac N8TT

Well, at this point I wouldn't bet the farm on the base cause being charged partcles impacting the antenna, but if it walks like a duck and quacks like a duck...

However, for this particular effect it is obvious that it is quantized and that the rate of generation is directly proportional to the wind speed.

Since there is nothing in the air large enough to be visible, it would seem reasonable that whatever is delivering charge to something is dust particles.

The number of dust particles in the air is also directly proportional to the wind speed, lending further credence to the theory.

As to how to test the theory, fooling around with the TV antenna on the roof with 40 to 60 knot gusts isn't going to be done by me no matter how much beer you provide.

One thought would be to make a pair of channel 2 dipoles with one inside a non-conducting dust cover.

Put the two antennas side by side and compare the results seen on the TV screen.

Another experiment would be to build a full sized dipole and a shortened loaded dipole for channel 2.

If the effect is caused by particles impacting the antenna, the quantity of snow would be proportional to the antenna sizes.

It would be interesting to see what happens.

In any case, Santa Ana winds don't normally appear this time of year, so there are about six months to come up with a definative experiment.

And yes, if it is simple and cheap enough, I'm willing to do it.

Unfortunately, one poster here apparently thinks if he cannot
see it, it doesn't exist. Presumably, if he ever goes blind,
even his ham transceiver will cease to exist. :-)

He reminds me of a governmental expert who said yesterday
on Foxnews: Since the successful kill rate for our anti-ICBM
missiles is 60%, we have to fire two of them to be sure we
shoot it down. :-) (After all 60% + 60% = 120% and wouldn't
that be overkill?) :-)

> And yes, if it is simple and cheap enough, I'm willing to do it.

I indirectly performed experiments in curing my arcing problem.
I replaced the bare wire with ordinary 600v insulated wire. It
reduced the problem considerably but didn't cure it. I then found
an antenna wire called "quietflex" at a hamfest that has 1000v
insulation. To the best of my knowledge, that cured the problem.
There is apparently a thickness of insulation that prohibits
the transfer of charge from dust particles.

84%. the "expert" might borrow a copy of Innumeracy.

the astute reader will note that this figure may not work in the real world.

probabilistic methods can be reliable. for instance, primality testing.
you can get the possibility of error down to 0.0000001%. but harder with
missiles.

they still use MIRVs with a hundred dummy warheads?

the Patriot was $1 mil a shot as i recall.

Source record: 57209

The thickness of insulation on an antenna wire does not entirely reduce noise due to (charged particle) precipitation.

There are two capacitances involved - the self-capacitance of individual isolated particles and the much greater capacitance of the insulating material between its surface and the wire.

When it impacts with the thick insulation, the electric charge on a particle redistributes itself between antenna capacitance and particle capacitance.

Only a very small fraction of particle volts is transferred to the antenna via antenna capacitance. The result is a reduction in receiver noise.

For given particle volts, size of particle, thickness of antenna wire insulation, permittivity of insulation, the noise induced in the receiver is calculable.

As Roy would insist on, to prove the point, all you have to do is measure the average volts on a particle of average diameter.

And the best way of doing that is to work backwards from the S-meter. ;o)

A nice, low noise antenna can be constructed by removing everything from the inner conductor of a 1" diameter coaxial cable except the solid polyethylene insulation.

This is an expensive operation, likely in the UK to of use only for 15 minutes every few years. So nobody bothers.

Yes, I assumed that was so, but in my case, it reduced the
noise to an acceptable level under most conditions.

No, Cecil, it seem that *you* misunderstand. My point was that you quote 100 uA/cm^2, and it takes very little current to achieve that with a tiny point.

But, nevermind. This has become pointless.

How much current does it take to achieve when a tiny
point doesn't exist? Can a dipole made out of #8 wire
with rounded ends exhibit corona during receive? If not,
the other side loses the argument.

I suggest you study exclusive Vs inclusive arguments.
The other side is saying that RF noise due to charged
particles is *always* accompanied by corona no matter
what antenna configuration is used. I am saying it is
not always accompanied by corona.

Tiny points exist everywhere, all the time, whether you wish it or not.

So, did you make any calculations? Did you even try to refute your own hypothesis? Have you looked at this from any other viewpoint?

> I suggest you study exclusive Vs inclusive arguments.
> The other side is saying that RF noise due to charged

> Lee......G6ZSG.....

Lee,

Try mounting your loop horizontally instead. Look at the MFJ mag loop.

By doing so, you will have a significantly lower pattern of radiation from your loop. You can also use a remotecontrolled LC network to change directivity of the mag loop without a rotor. However, it's simpler with a rotor.

To avoid skewed directivity from your loop, you can feed it with a balanced, dual gamma match. Combined with a RF trafo with a centre tap on the secondary side (antenna side) connected to the zero point at the loop, you get a more equal pattern of radiation.

Don't bother increasing the mount unless you have electrically conductive objects nearby. A loop does not need a groundplane.

As long as you can remotely tune and direct your mag loop, you actually have a rather good antenna. Don't listen to much to these who have acres of land and no neighbours but have fun making QSO's instead!

Cheers

Dan / M0DFI

4782. All Band Coax-fed Dipole ??????????

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-25 00:45:43 UTC
From: tomk3mov@yahoo.com
Message-ID: <1151196343.440223.242020@c74g2000cwc.googlegroups.com>
Source record: 57224

The BuxComm Antenna Company sells what it calls an All Band Coax-fed Dipole.

http://www.commparts.com/catalog/product_info.php?cPath=9&products_id=114318&osCsid=a84f7ccef1c8c9d59effad91005875fb

It consists of 135 ft. of wire, a balun at the center feed point, and the RG 8X coax transmission line. I don't claim to know a whole lot about antennas, but this configuration is contrary to everything that I have read about feeding mutiband antennas. When I wrote to the company with a question about this, I received a response from K4ABT, Buck Rogers himself. He attached to his note a section from the ARRL Antenna Book, which seems to indicate that coax should not be used with this type of antenna if one wants to use it as a multibander. I have a lot of respect for Buck, based on his years of Elmering a lot of us through his articles. But this one has me stumped. Any input will be appreciated.

> support and motor driven cap........

I assume the tubing is very well connected at the joints? Copper tube?

What type of capacitor? How are the connections made?

Turning the loop horizontal won't help unless you can get it up 1/4
to1/2 wave or more.

Close to earth you are better off with vertical, and the mat will help
efficiency although it is pretty deep for higher bands.

It all goes to the meaning of "works".

You will need to make your own mind up about what losses are
acceptable.

You should expect that the feedpoint impedance of that antenna at
resonance around 7MHz is about 4200 ohms.

The loss in 25m (~75') of RG8X will be about 8.3dB, or about 15% of
your transmitter power reaches the balun.

If you used a quarter wave of RG8X, the worst case line loss is around
0.7dB (or about 15%) per meter near the transmitter, that indicates
60W/m dissipation in that region at the 400W continuous power rating.
I doubt that RG8X is suited to this antenna on 7MHz at 400W
continuous, but with the lower average power level of voice SSB, it
should not be an issue.

The balun power rating and losses are another issue with this load
impedance, but in the absence of detail on the balun design, I will
say not more than more information needed!

There was an article in QST some time back visiting the issues with
multiband operation of a dipole with coax feed. The article was
centred around a 66' dipole, but the lessons apply to your prospective
purchase. I wrote an article at http://www.vk1od.net/LOLL/index.htm

reviewing the QST article, there are links to the original article and some other relevant articles at the bottom of mine.

Owen

PS: Nothing here is to suggest you wont get QSOs.

It is probably one of those clever bits of web technology that use
dynamic URLs so that they can't be passed on or linked (probably to
frustrate discussion like this)!

Search for 8010ABD100 on their home page.

Owen

Is the capacitor a butterfly type?

How do they keep current out of pressure contacts?

Why did you only make it 3 feet diameter, because you wanted to use higher bands like ten meters?

How are the connections made?

You know of course even the physical size of the cap (if physically large) can greatly affect loop efficiency.

It's nearly impossible to make a small loop work like most people predict. Lots of things can be problems.

even if you aren't touching something you have a much larger surface area to act as a capacitive path to ground for the rf. the small bird being a long distance from ground and having a smaller area has much smaller capacitive currents.

You could probably hang by one hand from a 20 kV power
line and be OK as long as you didn't complete a current
path to another wire or ground.

Hi Frank

Although ot answering your question I thought I might relate a recent experience of my own.

I remember various RF burns over the years. I never however thought I would have an issue with a 18dBm (<100mW) 11GHz TX I work on in my employment.

The fault was low output and I was doing an initial feel around with my fingertips, not actually touching an active citcuit metal but looking for excess heat. I then rested my finger on a small screwhead (maybe M2.5) that held the PCB down neear the output stripline (after the MMIC) and got enough of a burn that it felt like a static discharge spike one gets from a nylon carpet. It was a whoppa and totally unexpected!

I never did try to reason why the burn happened. The screw was loose about 2-3 turns so I am thinking a tuned cct of some kind with my finger as part of the dielectric! Oh an tighting the screw solved the low power problem!

Cheers Bob VK2YQA

From: Yuri Blanarovich <K3BU@optonline.net>
Message-ID: <%Dwng.1304$Ym7.135@fe12.lga>
Source record: 57144

Two major things involved:
1. Depends where you (bird) is touching, you are prone to get more pronounced burn at the high voltage part of circuit (coil, antenna). Higher impedance point - higher voltage - easier, more burn or draw the arc. We used to light up cigarettes by keying the transmitter, touching with pencil the "hot" end of the tank coil and drawing the arc, while puffing. W8JI might argue that current/voltage is ALWAYS THE SAME along the coil, so stand by for more scientwific 'splanation :-)
Anyone trying above experiment can easily see that it is easier to draw the arc at high voltage (low current) end of coil than vice versa.

2. Depends on the area/mass (capacitance) of what is touching the RF hot part of the circuit. Fat person vs. small bird would make a big difference. If one end of the person is (capacitively) grounded, the more pronounced effect.

You should have seen the TV educational channel where in some countries they have a basket type trolley that men are put in and hung by helicopter on the multi megavolt lines. They do wear some kind of suit that is conductive so the charge will not affect their body so much.

your term ONLY includes nuclear potential energy.

at ordinary energies, your expression is the correct approximation!

Early in this thread "conventional accepted physics" said that corona could not exist in fairweather conditions. Now there has been a subtle change to the theme of "prove that corona occurs in more than 99.9% of all cases."

Enjoy the banter, John, but don't expect to ever get Cecil to agree on anything.

The antenna pattern is highly predictable using modeling software.
The transmission line losses are probably not as high as Owen predicts
since we do not know the value of the attenuator inside the balun.
I have seen at least three antennas that had attenuators in antenna matching
networks in order to meet wideband VISOR requirements. These included
a 25 ft marine whip, and a military vehicular antenna. All you need is a
3 dB pad for 3:1 VISOR.

Giving a power rating to a dipole is suspicious also; although voltage
breakdown may be a factor. Note that it is rated at 400 WE "ROMS"
-- whatever the heck that is supposed to mean.

Regards,

Frank

he would have to model the antenna, then figure out what beam headings he desires, then find supports for the antenna. this is IMPOSSIBLE on most sububan lots.

you can burn up 6 dB in an antenuator and RG 58. and that's if the SWR is 1
to 1.

if someone has interest in 28 mhz, just put up a rotatable dipole too.

ya know, an auto tuner is a fun toy. mine is a Yaesu, and when i change
frequencies it remembers the values and coax.

highly recommended but more expensive than using a decent antenna.

Gene Fuller wrote:
> Early in this thread "conventional accepted physics" said that corona
> could not exist in fairweather conditions.

Actually, I said my references indicated that, but
that's past history. I later fine-tuned that concept
to "Corona cannot exist without an extra energy source
besides the fairweather current." Remember - moving
airplanes, etc? Please try to keep up. When I am wrong,
I immediately correct my error. That's the scientific
method in action.

My assertion is that charged particle noise can exist
without corona and that is most probably under fairweather
conditions.

I suggest that you and others review the logical difference
between exclusive statements and inclusive statements.

Exclusive statement: Charged particle noise cannot exist
without corona. A mostly meaningless statement since it
is virtually impossible to prove. Your side has been
asserting these types of exclusive statements.

Inclusive statement: Charged particle noise can exist
without corona. Easy to prove since it only requires
one example.

On-Glass mounts work quite well - HOWEVER Antenna Specialists (Cleveland based) - who has the trademark (and patents) for On-Glass antennas -- had significant problems with southern US installers -- who installed these antennas in high humidity environments (often outdoors).

I have installed mine on 3 different automobiles - since 1986 - NONE have fallen off after 200,000 + miles ... and I have hit tree limbs, car washes, etc. The aerial may have been bent - but the mount held.

They had an entire web page (old web site) to address the proper installation, etc.
They actually specified to southern installers to perform these installations in air conditioned bays (with the rest of the radio install).

"Copy cat" imported products also flooded the market -- with no instructions or real understanding of the correct mounting techniques - many consumers / installers were obvious to these differences. "OnGlass mounts are bad". "I had a bad experience", etc.
http://www.antenna.com/product_overview_detail.cgi?id_num=10418&styleid=6

Just another version of the Bad Capacitor situation -- buy and select for price (with no understanding of the fundamentals) - because they all look the same.
http://www.badcaps.net/causes/

PCTEL in Chicago purchased Antenna Specialists a few years ago.

Hi

In Europe the outside parts are normally glued to the glass using a silicone adhesive.The sticky tape is only used on the inside. I have succesfully remounted 2 metre antennas using silicone adhesive. Use an adhesive intended for wet environments (e.g. intended for caulking bathrooms or aquariums).

It's the current which matters.

The bird has a capacitance to the rest of the world which depends on its size. The current which flows up the bird's legs is the voltage on the antenna divided by the capacitive reactance of the bird's body. For small birds the capacitance is only a few picofarads and so the current is extremely small. The bird continues to sing its happy song.

Whereas, a human body not only has a much larger capacitance it may also complete the circuit by having the other hand in contact with grounded metal work. Or the victim might be standing in his bare feet. The current due to capacitance of the human body alone is enough to cause burns. The pain is sufficient to stop the human from singing and begin using bad language.

Reg.

That implies there is an attenuator inside the balun. I don't believe
we actually have any information with which to better understand the
balun.

Frank, in the absence of information on the balun, I did model it as
ideal, and that the load at the load end of the coax was 4200 ohms.
That is probably a reasonable assumption.

A real balun would not perfectly isolate the transmission line from
drive so influencing feed point impedance , and would probably
transform the real feed point impedance to something different to 4200
ohms, and so the line losses could be different (better or worse).

If the balun was built with substantial loss, it would tend to reduce
line losses, and yes, 3dB of loss (which would affect performance on
all bands), would improve the performance on 7MHz (though that balun
doesn't look like it contains a 200W dissipater).

All in all, the configuration, although used widely, can be expected
to perform poorly. IMHO tomk3mov@yahoo.com was right in being
suspicious of the product claims.

Hi fellow amateurs,
I am using 746Pro for 6M with direct coax to my 5 el antenna. I used to get 1:1 SWR but recently, the SWR runs a little over 1:2 and my output drops to 30W.When stations in FN20 were working EU, I could hear nothing. My signal can still be received because I was able to make contacts despite 1:2 SWR as far as FM5AA. But I know something is wrong with the line or the antenna. I checked all the connections and they seemed to be ok.

Can someone help by directing me to a source where I can read about troubleshooting transmission line? Or can someone who has experience in this give me step by step instruction on how to diagnose the problem, e.g., is it the PL 259 at the rig side, or the antenna side, or somewhere along the line, or is it the antenna altogether. I have an ohm meter and a small swr/pwr meter box.
Thanks in advance.

73, steve

Steve, If you can locate someone who owns an antenna analyzer you should be able to analyze your problem. I use the MFJ 259B.

Someone in your local radio club should own one, antenna analyzer, or have access to one.

BTW, a 2:1 VSWR is not BAD. It indicates that the antenna is receiving 90% of the available power. However, ICOMs are designed to power down on low to moderate VSWR. Note: I run about 30:1 on 75 meters.

< snip >

Yes. One of the standard tools used during RADHAZ inspectiions at RF transmitters sites is an RF Burn Gun. (It's shaped like a gun for convenience of holding and use.) It measures the RF potential on metallic structures near a transmit antenna and the tech is part of the circuit, coupling to ground. Current limiting in the RF Burn Gun keeps the tech from harm while he reads the potential off a meter in the "gun."

It strikes me that the measurement accuracy varies with operating frequency and size of the tech (via collective X-sub-C). With my big butt and short legs, I might offer more coupling to ground than you scrawny people.

On-Glass Reinstallation kits and coupling boxes.
http://205.234.153.66/images_product_overview/pdf_docs/reinstallationkit_p496.pdf

While the tape is part of the solution - the KEY step is the silicon
adhesive.

SOME automobiles are not appropriate due to tinting, special glazing used -
contact PCTEL A/S for details.

I am inclined to agree with you Owen. I was being a little facetious
about the load. I also noticed there is not a single specification on the
web site, except for power ratings. (Including the irritating term
"RMS power"). Incidentally 750 W into 4200 ohms represents
2.5 kV peak. If the balun is a real transformer it must be well
insulated.

it appears that buxcomm is owned or operated by K4ABT. i have talked to him
several times.

he has a lot of history in the ham community.

Super Glue will not stand up outdoors- maybe 2 weeks- but the real problem
is that it is so rigid that it will likely crack windshield glass (not rear
window) because the rate of expansion/contraction of the mounting foot is
different for that of the windshield glass.
The makers of the rear view mirror button and cement went to a great deal of
trouble to ensure that the scintered metal foot and the anaerobic cement
both had the same coefficient of expansion as the windshield glass.

Of all the techie things I could relate to, here's something I never thought would come up: I WAS a janitor at NSA. I was stationed there 1970-1972 as a Sailor and during my last 8 months, I worked as a janitor after hours to make enough money for the down payment on my first house. All the janitors needed to be cleared, which made us military folks shoo-ins for these jobs.

The pay was OK for your average part time job. Nothing special, but I was happy for the $1800 I banked in less than a year. (5% of 33,000 used to get a family into a house. Not today.)

My first wife still has that house and it's worth $700,000.

What coax?? I didn't say I used coax. I said I run about 30:1 VSWR on 75 meters.

I use 600 ohm open wire tuned feeders. My TL Loss, approximately 150 feet, is measured at slightly over 1 dB. I've been a ham since before coax became commonly used. <g>

Hi Owen,

Buck wrote a column in CQ magazine for awhile a few years back and abruptly left. Don't know the reason, but I did read some of his writings and some were just plain nonsense. For example he advised his readers that they needed to tune their transmission line if they wanted the antenna to work properly. After a few like that I just stopped reading his stuff.

By the looks of his antenna advertisements I made the right decision.

... and if it is a "voltage balun", a much higher flux level (~1300%)
than it would at 50 ohms.

Considering the information given in the product data, it leaves one
with doubts about the suitability of the recommended coax and the
supplied balun, and the performance of the entire system.

Try offering two outfielders and a pitcher to be named later :-)

Seriously, other than her half of the house (her current hubby got on the deed a few years ago for a re-fi), almost nothing. I divorced her in 1981 and traded away my half of the equity for no claim by her on my future earnings (meaning no spousal support and no splitting of my Navy retirement). She took a second to buy a business, which supported her, although she did not run it well and she took a loss when she sold it.

I doubt she ever saved a penny. She draws a Social Security disability pension for several ailments, real or imagined.

I fared better ;-)

My opinion would be that you'd be much better off if you want a single
wire antenna fed with coax going with one of the off center fed models.
the SWR is much better on many bands than the center fed model.

But if you must have a center fed model then you'll need to feed
it with open wire line of some sort .. coax just is not going to perform
well for you in a single wire all band dublet. the Losses on most bands
are not good.

There's too much fuss made about resonant length of simple wire antennas.

(1) Radiating efficiency is hardly affected by being as much as 20 or 30 percent off-resonance in terms of antenna length.

(2) The feedpoint resistance at resonance may indeed provide the theoretical correct termination for the transmission line for 1-to-1 SWR in the middle of an amateur band. But it is way off resonance at the band edges with an SWR which causes little if any concern.

(3) The impedance of the transmission line is usually known only approximately. The reactance of Zo is always ignored. So exact SWR on the line is never known. SWR varies slowly with small changes in antenna off-resonance length.

(4) If an antenna tuner can accommodate changes in input impedance from one band to another it can certainly accommodate the omission of the correction factor 468/F.

(5) So it hardly matters whether the correction is applied or not. The minute difference in operating performance will be detected only by an impossible A/B test. You can put away your pruning shears.

The theoretical resonant length of a 1/2-wave dipole is 150/F metres. The actual resonant length is very slightly shorter.

In free space, the shortening depends on length-to-diameter ratio of the antenna conductor. But at low heights above ground the shortening effect increases.

When the antenna wire is lying on the ground its velocity factor is approximately 1/2 of the free space value of 1.

So you see the formula 468/F, although good enough for most purposes if you want to use it, is very approximate.

The question is about the resonant length of a 6m dipole.

Is the dipole 6 metres long or is it resonant in the 6 metre amateur band? Questioners should make themselves clear.

Assuming it is 50 MHz, resonant dipole length is very nearly 150/F metres = 3 metres.

But the answer depends on conductor diameter. If frequency is 50 MHz and the antenna is constructed with 14 gauge wire then the resonant dipole length is 97 percent of 3 metres.

If the anenna is constructed of 1", 25mm, diameter tubes, then the resonant length is a little shorter. It is 94 percent of 3 metres.

But actual lengths are non-critical. You can use a tape measure or a wooden ruler. And don't worry if you can't find your spectacles.

Reg.

There's a great difference between working on antenna conductors and 60 Hz power lines.

Body capacitance is all-important at HF. At 60 Hz it is the conduction path which matters. Workmen can be enclosed in Faraday screens.

I just waded back through my postings. A day or two after making
that statement, I added the context in which that statement was
made. (That happened days ago).

Conventional accepted physics says that corona cannot exist in
fairweather conditions without an additional source of energy.
When I asked that the source of corona energy be identified,
I believe it was you who said, "Who cares?". So I ask again.
Given fairweather conditions, what is the source of energy
for corona? In matters of politics, one follows the money.
In matters of physics, one follows the energy.

Greetings.

If we are using one low power FM transmitter and we want to use a 2-bay FM antenna configuration, will using a power splitter at the transmitter output be sufficient?

The FM TX utilizes a type N connection to the FM antennas. .... So if I split the power output and just have two outputs to handle each of the two antennas, then that would work right?

What other considerations should I have in mind? Do I need to worry about phasing issues?

Thanks!

Frank isn`t using enough power. I worked in a shortwave broadcasting plant filled with 50 KW and 100 KW DSB fully modulated transmitters. Our relatively flat transmission lines were of the 2-wire unshielded 600-ohm variety. These lines must have attracted countless tired migratory birds to alight or try to alight. When a bird would try to grasp a wire, it would instantly be consumed in a puff of smoke and steam. No carcass fell to the earth. Poof! it was gone. Many times their claws were left behind gripping the wire leaving us a record of the bird`s visit. Many wires were covered with bird claws. RF can kill more birds than cats can.

Best regards, Richard Harrison, KB5WZI

if the OP has no antenna or coax problems, he might invest in an antenna tuner.

http://www.ocarc.ca/coax.htm

example follows.

100 watt transmitter
30 watts out
50 feet Belden 9913
2:1 SWR
26 watts to antenna

much better than coax.

i had no easy way to run twin lead through my window, so i used RG 58. my
losses were bad.

At any hardware store, you can buy a drill that will put
a hole through glass. That's pretty easy.

True. The question being asked is "How could it be possible to hear such tiny charges impacting an antenna?" It is just as reasonable to ask how could it be possible to detect the presence of tiny electromagnetically induced currents on an antenna. But in consideration of the latter, it should be apparent that if the magnitude of the randomly fluctuating ion current approaches that of a small electromagnetic current it would be impossible not to detect it.

A true coax fed "dipole" needs to see a 50 ohm load on
any of the bands to be used. Well, unless you like to lose
a lot of power on some bands. :/ So it would be better to
use an auto tuner at the feedpoint. It would be even better
to decide what bands you *really* intend to use, and run
dipole legs for each band in parallel. Spread wide apart
is better than stacking them on top of each other with
spreaders.
The antenna as they sell it is pretty micky mouse for an
"all band coax fed dipole". As one mentioned, the loss on
40m could be large if you feed with coax to a high Z load.
The antenna they sell would be best run using ladder line
all the way to a tuner, or tuned by length. Seems like you
say they mentioned this, but then why buy the uneeded
coax, choke, etc that you would end up discarding. ?? :(

> In matters of physics, one follows the energy.

Cecil,

I said that one could use either energy or forces (fields) to solve most problems. (I have said something similar several times in the past.) It is often much more convenient to use one formalism over the other due to the availability of numerical information and workable boundary conditions. If the problem is set up correctly and the math is done correctly the same answer will result from either formalism.

If you want to solve the corona question by "following the energy", have at it. Go ahead and set up the correct boundary conditions, figure out the right equations to use, and just plug-and-crank. Piece o' cake. The only minor issue is that the atmosphere can act as a effectively limitless source or sink for energy. But I am confident you can find a way around that little detail.

By the way, I would sure like to find that reference you have for "conventional accepted physics." I have a library full of physics books, all of which seem to be conventional and accepted, but I have not found one that has such as all-encompassing title.

73,
Gene

Ooooo Saw the call and had to comment...

I have a 40M inverted Vee up around 35 ft. . I have had out of state
contacts on 75, 40(DX), 30(DX), 17, 15, 10 and 6. Is it a "good" antenna?

I wish I had better, but it "works". Do I think it is a great antenna? No.
Do I think it can be called efficient on the other bands? No. Do I think
it has lots of lobes on the higher frequencies? Yes. If I can hear them, I
can usually work them. OK by me... Do I have room for better? No.
I got much more than what I paid for $0.00. You can probably do better with
a "fan-type" dipole. I keep thinking I should at least add 75M wires and
20M wires. When I have time... . . . . . .

The antenna in question is similar and just as inefficient on some bands and
has many lobes on others. It'll get you on the air if this is what you want
/ can afford.

Dave... I used to talk with KC9DI on 2M. We'd say the calls as fast as we
could, just to confuse the random listener...(:-)

>
> Thanks!
>

You need to move the splitter closer to the antennas in order to save
power losses. You you need to worry about phasing but that is taken care
of when you run the coax from the antennas to the splitter cut the coax
to approx. 1/2 wave. See the ARRL antenna book.
You will have a change in impedance in this configuration from the
splitter to the antennas. Look at about 70 ohms to the antennas and use
50 ohms from the transmitter to the splitter.
I am sure that other helpful assistance will be forthcoming from others.
Turn your BS filter on.

and also the dipole is shorter because you want to cancel out the reactance.
a "real" half-wave would have a resistive and reactive component.

i think if you get into big tubing or pipe, you get too much reactance.

> > The theoretical resonant length of a 1/2-wave dipole is 150/F metres.

i should have thought of that.

c = 3 * 10^8 m/s
F = frequency / 10^6

465/F theoretical (feet)
468/F practical

i think i made a math error.

I presume this is a CushCraft with a Gamma match, and an SO239 connector for the feed. I have a CC 2meter antenna where the SWR shot up. Turned out to be the shell of the SO239 not making good contact with the Gamma bracket. Could also be something loose in the match itself.

If you are using the original 9913, it could be full of water.

It would also be useful to find out if you still get maximum gain off the front of the antenna. Do a 360 on one of the beacons, and record the S meter readings

Before doing anything at the antenna, I would look at the coax and see if there is any visible damage, like from squirrels. The next easiest thing to do is to whack off the PL259 on the radio end, and very carefully install a new connector.

Ignore the crap about high SWR being OK. It's not OK for a 6m beam that used to work.

Tam/WB2TT

Perhaps the 4200 ohms is reasonable, but the assumption that the balun is ideal when connected to that load impedance is most definitely not. Any result you get when using that assumption is useless.

A real balun would do all those things, in addition to adding reactance and, at that impedance level, loss.

> appreciated.

I believe the antenna will be quite inefficient on some if not all
bands, either by accident (a balun which becomes lossy when confronted
with extreme impedances) or intent (a resistor inside the "balun"
container). If so, it's possible you'll get a reasonable match on all
bands, and nearly certain that you'll be able to talk to some people
when using it. But it also means that your signal will be considerably
weaker than it would be if you were using an efficient antenna.

I know what you mean about Elmering. Many of the new hams had to Elmer the old CW only hams who had no idea how to operate a computer or even use all the great new digital modes. Some of the dinos had trouble trying to figure out the solid state rigs. They kept looking around for things to tune like it was some boat anchor tube rig - LOL!!!

It's amazing how the dinos can operate a key, but they can't get the hang of a mouse. We eventually had to give up. Can't teach the old dogs new tricks so the younger and newer hams used the digital modes and the old dinos stuck to their CW.

Although the CW types were amazed how PSK31 could be copied even when you could not hear the other station. They admitted that you can't copy CW if you cannot hear it.

I think we made a lot of progress on FD. Finally the dinos admitted that there are modes that are better and more capable than CW.

One old guy even said we should give up on the CW testing and test new hams how to use a computer and the new digital modes and that was more relevant for today's ham radio.

Cecil,

Why should there be a simple answer?

I already told you that is not the path I would take if I wanted to find a quantitative solution. You might check your "conventional accepted physics" references if you are looking for a simple answer. On the other hand, if those references consist only of hand-waving explanations, common sense logic, and quotes from legions of experienced radio amateurs, then you may need to do some actual work to find your answer.

I have a similar situation. I have come to believe the most important thing to do is assure that all of the ground rods are connected. I have power, phone and cable service underground. I don't think I have had a significant strike since last August when I had a company install lightning rods on the house. They were very careful to ground the base of the tower to one of their rods. They installed Galvanized rods.

Another good question is whether to ground the rebar in the tower base. I elected not to worry about it but to focus on tower grounding.

I wonder about the dishes on the tower. In times past mounting them too high mad them vulnerable to terrestrial noise. The wind load they contribute can be awesome.

I'm installing a 60ft self-supporting tower. It will have a vhf/uhf antenna with rotator and a couple of satellite dishes on it. The tower will be set in a concrete apprx. 4'x4'x4'. Is driving a copper clad 5/8"x8ft ground rod and attaching a #6cu ground wire to the tower leg sufficient.
I live in a heavily wooded area and have lost several modems to lighting strikes. Now when it looks like thunder 2 states away I unplug them on my computers and Directv receivers.

You could probably hang by both hands if they were close together. I
would not want to try it, though.

When I worked in broadcast radio years ago, I was always amazed that
service personnal would climb the 10 kw tower hot to change lights.
They stated they could feel potential between their hands as they
climbed.

What you described will do little for lightning protection except give
you a false sense of security. Surviving a direct hit requires much more
grounding and proper treatment and routing of all cables into the house.
I would highly recommend spending $20 on PolyPhaserï¿½s book of info or at
least reading the tech notes on their web site.

Motion of one material against another. Silk/glass, dust/metal, rubber belt/metal combs.
They all transfer electrons from one object to anther.

That creates charge. But what is the threshold for CORONA. Charge and corona are two different entities. Isn't corona entering the realm of plasma physics?

Your response doesn't answer the question.

Check with your local building inspector. The National Electrical Code and your local zoning have requirements for proper grounding.

Basically, the ground at your home is the ground rod at the service panel for your electrical service.

When I installed my last tower each leg had to be connected to an 8 foot ground rod with #6 AWG. Each of the ground rods had to be interconnected. And, the total connection, towers and rods, connected to the service entrance ground by #6 AWG run EXTERNAL to the house. [Keep current OUTSIDE the house]. This met insurance requirements. But, as mentioned in another response, it does little for protection from a nearby or direct lightning strike to your radio equipment.

I was taught that the BASIC source is the energy from the FUSION device that can be seen on a sunny day as it interacts at the atomic level with 'stuff' :-)

But, I don't think that's what you are asking!

Yes, if you have one rod and attachment run outside the tower base block for each of the tower`s legs. This has worked for me countless times with good results. Usually my ground wires were larger than #6 AWG, but I think #6 is likely large enough to work well. The tower ground must be well connected to the electrical service ground to meet code and ensure the potential difference between grounds is insignificant, even during lightning strikes.

Best regards, Richard Harrison,KB5WZI

Exactly. Whether one particle can cause a detectable noise
pulse obviously depends on the charge on the noise particle
and a number of other parameters.

But given, e.g. a coax fed dipole with the coax braid grounded,
a difference is charge is likely to occur between the elements
that is large enough to be heard.

Gene Fuller wrote:
> Why should there be a simple answer?

Because conservation of energy is a very simple concept.
Energy either exists or it doesn't. If it doesn't, corona
is impossible.

> I already told you that is not the path I would take if I wanted to find
> a quantitative solution.

I know that already and your particular quantitative
solution explains absolutely nothing about reality so
it has to be taken on faith. Quantum physics is currently
filled with such solutions. Nobody can prove that virtual
photons exist because if virtual photons could be proved
to exist, they wouldn't be virtual anymore. That's essentially
the same argument you are using. "Forget energy reality and
place your faith in my religious mathematical model that
doesn't require any energy". Sorry, but no thanks.

surely you mean virtual particles like electron and positron pairs. i
believe these are mainly a construct to simplify calculations.

for instance, Heisenberg had a different approach than Schroedinger.

Full text was at:
http://buyit.philly.com/findit/search/results.jsp?catId=krd_philenqda...

This was a new on-line ad placed in Philadelphia Inquirer and
Philadelphia Daily News on www.philly.com (see full text below)
It was about the secret aerosols rooms in US. One could find it by
searching "secret", say, in the ad section of philly.com.

Democracy can not function effectively without the informed public. As
a former NASA Langley scientist working in the area of nanotechnology
and nanoscale particles, I have been recently exposed to the
establishment of secret gas-aerosol rooms inside of United States, at
least in the Mid-Atlantic region (from Philadelphia to Virginia).

First, the highly irritant aerosols have surfaced at the NASA Langley
Research Center in several safety accidents. Investigations were
blocked, probably, because of lack of Congressional approval for such
financially-lucrative research at NASA. Later, these aerosols had been
encountered outside of NASA in Virginia, Delaware and Pennsylvania
.
This points out to yet another proliferation of originally-sensitive
technologies into domestic American life to hurt and harass people
without a proper oversight and much control. This amounts to torture,
extra-judicial prosecution and authoritarian intimidation tactics. The
use of such irritants and the operations of the secret gas-aerosol
rooms are gross violations of human and constitutional rights of
American citizens and various domestic and international laws.

----------Full text of an ad from

4950. Small City-lot 160,75,40,20

Newsgroup: rec.radio.amateur.antenna
Date: 2006-06-27 19:18:53 UTC
From: gene@csl.uiuc.edu
Message-ID: <e7s0at$he9$1@news.ks.uiuc.edu>
Source record: 56992

As an older ham having lived on a small city lot in an older
neighborhood, I have only 45' x 55' of back yard for antennas.
Fortunately, my neighbor has a tall tree with a branch overhanging
my driveway. I have a nylon rope and pulley (used sling-shot) about
40' high on this branch.
I have done a considerable amount of experimenting over the years,
including wasting time on the infamous CFA (Crossed-field-antenna)
or "EH" antenna.
I recently posted my surprisingly good results with a mobile
configuration [search "Built Mobile using Lewallen "fat dipole" concept"]
and decided to see if I could emulate these results by using a
"surrogate vehicle". I happened to have a 4' x 11' sheet of aluminum
so I placed it on top of 1/2" styrofoam (non-foil) so that nothing
touches ground. (This is my substitute "truck").
The feed coax shield goes to the exact center of the aluminum sheet,
and of course the center of the coax to the insulated vertical antenna
going up toward the pulley.
This flexible pulley system conveniently accommodates 160, 75, 40
and 20 meters and works very well on all....especially causing some
head-scratching among the long established 160 meter groups who consist
mostly of high-power and optimally large antennas.
Of great help is the "Capacitive Hat" I use. Actually, it is dual
purpose, because it is a 6' diameter Hi-Q horizontal loop (Halo-type)
made from 1/2' aluminum tubing (surplus coax) with concentric tin cans
with teflon spacers as capacitor to fix-tune to resonance. A trim tab
is available when lowered. Its 5' BNC/RG58-leader is connected to about 75'
of RG58-U to reach the radio shack, and is hoisted with nylon struts
to about 35'. (I have been using it with 1KV SSB peak for about 10 yrs)
and it works very well because of decent low-angle omni-directional
pattern.
So this was very convenient to subtstitute as capacitive hat on 160, 75
and 40 meters. On 160 meters, a very Hi-Q loading coil is used at the
5' leader of the loop mentioned above. I used the same loading coil
that I described in the Mobile article mentioned above....with a few
more Hi-Q turns added. For the vertical conductor, I used the shield
of RG-8 (tied to inner conductor) for low-loss. I didn't measure the
shunt matching capacitor required to match feed point to 50 ohms,
but it was probably about 1000 Pf .
On 75 meters, I jumpered out (shorted) most of the 160 meter loading
coil for resonance, and reduced the shunt matching capacitor to
probably 400 pf, or whatever is required for very low SWR.
On 40 meters, no loading coil is used, and actually the capacitive
hat had to be lowered for verical height of only about 15' to
reach resonance, and very small shunt capacitance is needed....also

it covers the whole 40 meter band. I used RG58 shield because
I didn't have RG8 in my junk pile. I may later reduce the 160/75 to
RG58 also to reduce the weight on the small pulley that I installed
earler...I'm wondering if too much up-and-down might ruin the pulley.
I usually take my transceiver and SWR bridge out near the aluminum
plate for matching on 160 meters, which is more critical for top
performance.
As in the Mobile discussion, I still pass the feed coax (I use RG58)
with several turns thru some large ferrite toroid cores to minimize
currents from coming back on the outside of the feed coax...thus being
readily coupled to ground as loss.
My speculation about this good performace, is that the aluminum sheet
represents an infinite number of radials of equal and opposite
horizonal currents that minimize propensity to couple to earth thru
the 1/2" styrofoam insulator, and the voltages at the end of the
"radials" have very little corona-type loss as the voltage is
distributed around the sheet edges, and touch ground nowhere.

For those who find these performance claims credible, there could
be alternative ways of experimenting, such as figuring ways to make
good low-loss connection to "foil-sided" styrofoam sheet laying on
a "non-foil" insulator sheet. Or perhaps a series of aluminum-foil
spokes connected well at the center and laid on (or between) styrofoam.

But the a-c frequency is important here. The voltage gradient between adjacent hand grips for power in a conductor at AM broadcast station frequencies (the vertical antenna radiator, in this case) is a lot higher for the same conducted power than for that same span along a conductor on the 50/60 Hz a-c power grid.

Any really experienced ham knows that each and every mode has conditions
under which it is "the best". Ever try to work PSK when the auroras are
running wild? Digital won't get through but CW will and occasionally even
voice will get through even though all the digital modes fail.

You must have a very weird club.

I doubt it. Computers are nice (I use one all the time) but they are not one of the basics.

To begin with this is an antenna page, but we'll ignore that for now. I do happen to play with VOIP, a lot actually, so I'll go look.

Well, your link points to a page that covers a ton of subjects/mini white papers related to VOIP, none of which seems to mention amateur radio. And none of the pages are what I would consider useful. I'd say you need ask your question with more detail, or post a better link.

Meanwhile, see -

www.trixbox.org

for an open source turnkey PBX. Up in less than an hour (if you are familiar with telephony).

http://asteriskguru.com/tutorials/

for info on SW/HW which works under the Asterisk PBX. This is the SW PBX behind the trixbox distribution.

and

http://www.voip-info.org/wiki/

for the VOIP wiki.

That ought to keep you busy for a couple minutes.

Good luck.

Frank Alforo wrote:

> If I touch the coil in my tuner while transmitting I get a painful rf
> burn. But a bird can perch on my antenna wire while I transmit 100 watts
> and it stays there seemingly without a care in the world. How come?

Frank,

Some basics.

There are two types of RF radiation, Non-ionisation and Ionisation radiation. The HF bands are non-ionisation (normally) and the damage you'll notice is generated either from High Voltage or RF Radiation.

Look in the ARRL handbook on RF safety. Different parts of the body have different frequency ranges where we have extra absorption of RF radiation.

Touching a coil in the tuner? This type of RF burns are either primary High Voltage or secondary = induced or transferred via capacitance to a metallic object within the antennas RF field.
(Why the F**K do you touch a coil in tour tuner whilst transmitting!?)
Do you put your finger in your cars cooling fan too?

The result is tingling sensations and direct proportional of the power (or stupidity), different Voltages will occur. High Q antennas can have really nasty voltages, like magnetic loops.

High Voltage gives burns and can give nasty and very deep internal damages. Read your safety regs! You are supposed to know these regs as a ham!!!

Radiated RF.

Non-ionising RF radiation can be compared to sunlight. To much RF radiation and your body (or parts) will heat up. The effects are like sunstroke or prolonged exposure to hot climate. Short term effects are nausea and fainting - like a sunstroke!

A small bird will have problem with RF Radiation but less problem with High Voltage. unless both poles are present and the stupid bird touches both. Birds (as in flying small animals) have often none or minor problems as a difference from the other type of birds, that develops to YL's and XYL's...
(No, you are not allowed culling XYL's with RF radiation!)

Ionising radiation is a different matter and is what we normally call "radioactive radiation". The energy levels of this type of radiation is much(!) higher than normal RF radiation and if you don't know you are near areas with this type of radiation, you are either trespassing or plain stupid....

Generally, higher frequencies, especially in the microwave spectra, tend to contain high energy levels. Also, bear in mind that the frequency where water absorbs RF radiation is around 2.4GHz.

If you are inside a high intensity field, get out! One of the first things to be damaged in a high RF intensity RF field is your eyes. They might coagulate and I promise - that's a bad thing and most probably irreversible. The good thing is tho' - you don't need glasses anymore...

Another thing not to do is to place your glutus maximus over a wave tube with power on --- bollocks!

Now then....

Most accidents where RF burns and RF radiation exposure occures, creates damages from a fall, not by the RF radaition itself!

People tend to climb up on ladders and on masts before they decide to get zapped... Bad idea as most of them fall down and break arms and legs at the best...

/////

No, I'm not a safety freak but I have a valid certificate for work in masts and on rooftops where there are aerials...

Cheers All

Dan / M0DFI

I have created some software to create a radial map to help you know
where to point your antenna. A sample of the map can be seen here...
http://www.thewishzone.com/cdw/hamradio/RadialMap.gif

Pretty much any part of this map can be customized from the start and
end point of the radials how many degrees apart each one is, having
multiple sets of radials, such as a set every 1 degree from 97 to 100
miles out with an other set from 5 to 200 miles every 15 degrees. Any
number of sets of any length can be done. As well as circles of any
size. All very easy, just supply the center lat long. I can also print
the map any size up to 42" wide/high. I've never printed had any paper
that big on this printer but I do know it will take paper that big. I
would have got a 36" wide printer but it was too slow, and this one is
faster. With the software I am developing creating the map is very easy
but obviously printing it isn't cheap.

I'm sure I would too, that's why I am trying to contact them to see what they have to say first. I may just print up one for me and a few for some friends for the cost of using the printer and not sell them at all but if it is something a lot of people would find useful and it can be done for a reasonable price, then I will try to see if I can sell them.

Looking at the thing, I suspect that it is an OCF dipole. It isn't very clear, but since they have a "L1" and an "L2", that gives us one clue. Most center fed dipoles don't need an L1 and L2, because they assume center fed, inherently 2 equal sides. Notice that they also say "this is not a kit". That is a disclaimer that they put on their other OCF antennas. Finally that 135 foot total length is typical of an OCF dipole.

Dis ting is quackin' like a big ol' OCF duck!

And as such it should be a serviceable antenna.

Funny that some people are dissing BuxComm on technical matters in this case..... ;^)

OCF = off center fed?

i suspect the sides are equal in length. L1 and L2 are just designations
used in drawings to denote an element of some length.

Buxcomm sells a Windom too.

MRW -

Start with Radio World - for industry info
http://www.rwonline.com/

You need to understand more about antennas. Please look at (and learn from)
the methods used by commercial broadcasters - that have been at this for
decades -- they have taken the road of "least cost" and best economics".

2-bay and 4-bay designs are common is FM broadcasting and even used in the
Land Mobile Radio (LMR) Service. Amateur radio references can be invaluable
in learning the proper theory.

Mike, we (you and I both) aren't sure of the detail, and that in
itself speaks heaps for the product information.

Whilst you have drawn a clue that the unspecified L1 and L2 suggest
that they are unequal, I drew a clue from the description of a
component as "centre insulator with eyehook", and if that product
detail is accurate (and we take the ordinary meaning of the word
centre to be a point that is equidistant from the extremities) then it
suggests centre fed.

I still think on balance of the published info, it is represented as
an "all-band dipole" on "80 through 10 meters" and appears to be a
135' centre fed dipole with a balun (of unknown type) and recommended
RG8/X feedline. Such a configuration will be likely to have high
system losses on at least some of the bands with practical lengths of
feedline as discussed earlier in the thread by several people.

I reached over to adjust the capacitor not realizing that the set screw that fixes the capacitor knob onto the capacitor shaft stuck up beyond the surface of the knob shaft. My finger reached over and touched the end of the screw as I keyed down.

My free hand was not grabbing a ground wire. I was sitting in an upholstered chair which was on a rug which was on a wood floor.

And no, I do not put my finger in my car's cooling fan.

There's a free utillity called Pizza that does something like this.
What I like about it is , you can import your antenna polar diagram from
NEC etc and overlay that as well as the compass bearing. OK it's just a
line drawing map , but good enough for most purposes.

hello,
I am computer engineer from Nepal. I am currently working on a project about power flow analysis. Now I am having problem with procedure to calculate load flow. By reading some books I have used newton raphson method to calculate voltage drop at different bus of a very simple 5 bus system with no transformer on it. Now the problem is with the calculation of phase angle which is very large about 1000 degree and also negative sometimes . Also the convergence did not occur for large system with about 20 bus.

Again, today boss called me and said, the project which i find quiet confusing..
goes like this,
We have to bring power from source to the transformer and from there it is carried by transmission line. At regular interval on transmission line there is node(I think its a bus) from where it goes to the city.Now i have to develop a software which will simulate and give the voltage drop at each node and also need to calculate the maximum voltage that the transformer should give which the load can handle without "Black Out". He says to take data about cable including its length from feedeer and develop software.
I am having very big problem with this one.....so i want to know the detail step wise procedure to solve it so that i can convert it to programming code.If possible please send me the Algorithm or pseudo code to solve it.

Jeff;

Some years ago I destroyed a log of expensive ($1,000 each) IBM computer boards because I failed to install grounding devices at the exit from one building and the entrance of another building when I installed remote terminals for the company computer. There was a significant voltage difference between the two buildings even though they were only twenty feet apart and both were well grounded by themselves. I still had to install a bonding wire between them.

You will encounter the same situation between your tower and shack. A few feet of copper is cheap insurance. Three hundred fifty feet will generate significant voltage that may or may not cause you a problem.

Jeff,

You really need to go to professional sources and not listen to advice from random internet responses on safety issues. There is so much folklore and pure bunk that is accepted as fact that it can really get you in trouble.

Look at the polyphaser web site and read their techninal notes carefully.

The single most important thing is cable routing and bonding of equipment to common points.

Most lightning damage people get isn't from tower hits, it is from hits on power lines that flow back through the house to grounds!

Every cable entering the house should be grounded to ONE common point. That includes telco, cable TV, power mains, your station ground, and all your cables entering the house. That is a NEC requirement!! That's the single most important thing you can do to prevent damage.

Everything leaving the tower should leave at the tower bottom, and be grounded to the tower at the tower bottom, and that point shuld be grounded to earth. That's the single most impotant thing you can do at the tower.

The tower will be 350ft from my house's service entrance ground. After getting you-all's feedback I make sure all the rebar in the tower base is electrically connected and the rebar is attached to a perimeter ground system with a rod at each leg. I'm also researching what type of lighting protecting devices I will install on the coax, this may attach to my service entrance ground.

But I can't see the need to connect the tower grounding system to my service entrance ground when it's 350ft away. Was meeting the insurance requirements part of a spec. written in the policy regarding residential towers ? What section of the NEC deals with tower grounding ?

Afraid you have this wrong, gravity.

Consider:

P=today is my birthday
Q=I will receive a present

If (today is my birthday) then (I will
receive a present).

If (I will receive a present) then MAYBE
today is my birthday and MAYBE it is not.

Sorry, Cecil. I'm not following you on that.

Whether the statement P implies Q is
true has nothing to do with whether P is
true.

My point was that P implies Q does NOT
mean if ~Q then not ~P.

73,

Chuck

The Polyphaser book was the main source of data used by the company I work to redo the grouding at many of its sites. Most sites that were being knocked off the air nearly every time a storm came through have never had such an outage since the new grounding was installed. $20 bucks well spent. Installing the new grounds will cost a lot more. One of the big impovements was to use low inductance braided cable run all the way from the air terminals at the top of the towers to the ground rods/system. Prior to this the tower was grounded by a cable connecting the base of the tower to the ground system. Much more was done which included grounding coax and and control cables where they entered the building. This was done prior to the modification but there was now a much larger emphasis on LOW INDUCTANCE connections. Typical change made. Coax shields were attached to ground at the point they enter the building prior to the mod. This connection is still there but made through copper straps instead of cables and the coax is also grounded just before it makes a 90 degree bend to leave the tower and enter the building. Going from several lighting related outages a year to none in several years is a big improvement.

Dear MRW:
Do not do what you are proposing - assuming that I understand what you are proposing.

It sounds as if you propose to connect in parallel, near the transmitter, two transmission lines with each transmission line running to one bay of a two bay antenna. You are not too clear about what you propose.

It is very difficult to have two transmission lines that are many wavelengths long (as expected) that are so equal (including the termination impedance) as to have the phases of the two signals at the antennas be equal (as required by the normal two bay antenna). It is possible to maintain close phase equality with short pieces of coax that are near the antennas.

Tell us more about what you wish to do. Mac

Owen,

I found some information for this atnenna at

www.stroobandt.com/antennas/windom/windom.html

On the design attributed K4BT showing the dimensions to be:

L1= 13.4 meters (43.965 ft.)
L2= 27.1 meters (88.915 ft.)

Regards,
Danny, K6MHE

> Sorry, Cecil. I'm not following you on that.

Neither do a lot of other people. Here's the truth table
for an: (If A then B) = C logical statement

A B C

True True True
True False False
False True True
False False True

If the if-portion of an if/then statement is false,
then the entire statement is true, by definition.

For instance, this is a logically true statement.

If I were ever to play in the NBA, then I would be a superstar.

Since the A portion can never be true, the entire statement
is true, by definition.

In your earlier example, *both of these statements are true*
if you didn't receive a present. Only if you actually received
a present can one be true and the other false.

1. If I receive a present, it's my birthday.
2. If I receive a present, it's not my birthday.

> from that supports corona under fairweather conditions?

If the antenna is a vertical,
ungrounded, uncharged wire, it is a
conductor in an electric field (the
fairweather field).

The free charges in the antenna will
move so as to cancel the fairweather
field inside the antenna wire.

At the top of the antenna, there will be
a concentration of negative charge. If a
single strand of wire sticks out, that
concentration could be sufficient to
ionize the air and cause corona.

If the corona starting voltage is
typically 30 kV/cm radius, then a tiny
wire could ionize the air at only
300volts or so for a 0.01 cm radius.

http://home.earthlink.net/~jimlux/hv/corona.htm
Corona

Based on that, it would seem the
fairweather field can support corona
formation by itself.

If a charged particle now strikes the
uncharged antenna, free charges will
redistribute themselves to maintain no
net electric field inside the conductor.

The antenna's charge will increase until
it exceeds some breakdown threshold.
This process seems functionally similar
to that due to the existence of the
fairweather field, although either could
exist independently.

The question then seems to be whether the redistribution of charges that occurs when charged particles strike the antenna causes a current in the antenna which is detected by the receiver as noise. I believe this is the question Cecil has been posing.

It occurs to me that the current due to charge redistribution could be rather significant if numerous particles are striking the antenna in a short time interval. Even a corona discharge will cause a redistribution of free charges that may show up as a detectable current at the receiver. This would be a different effect from the noise generating property of the corona itself.

Any thoughts?

Chuck

Get a grip, of course I will have an agreement with the supplier of the basic map data. Forgive me for thinking that others mind find useful something I find useful.

I made this map for me and a few friends. If no one else wants one, then so be it. I just thought, since it is now very easy for me to make more, centered on any point, I would ask. Someone in another forum mentioned that they could tell you where any town with in 100+ miles of them was with in 15 degrees. If you are the same, I doubt you would find this map very useful. As for me, there are over 400 towns with in 100 miles of me and I have no idea where most of them are. With this map I can quickly look and see how far and in what direction places are from me.

As an update, I see that Llewellyn (not
W7EL) in 1975 established experimentally
that for a point radius of 0.01 cm, a
corona will be formed with fields of
only 100 V/m. These results differ a bit
from what would be predicted by
Paschen's curve.

Buxcomm's site does list a large number of antennas that are described as "Windom" antennas, but the one that is subject of this thread is not explicitly described in the product information as a Windom of any kind, or as an off-centre fed dipole of any kind.

There is an apparent desire on the part of some to construct the case that the subject antenna is a Windom on the basis of:
- designation of L1 and L2 on the diagram, although there are no values stated to show that they are unequal;
- that elsewhere K4BT has described "coax fed Windoms".

There is nothing conclusive on the diagram at http://www.commparts.com/catalog/images/products/8010ABD.gif to suggest that this is a "coax fed Windom", though some infer that is the case because of the L1, L2 designation though not values are shown.

I argue that designation of a key component separating L1 and L2 as a "center insulatore and eye hook" has more value than the undimensioned L1, L2 designation.

What is becoming clearer, is that on the basis of the information published on the commercial web site for this antenna, the buyer cannot be sure of just what he is getting, much less how well it might perform.

Owen

I have no argument with getting professional advice. I hired pro's to
install the lightning rods. They were in agreement that I should
always provide a protective ground other than my equipment. They had
no problem with the fact that I went through the basement ceiling with
a number 6 wire atttaching a cable TV ground to the power panel
ground. It was the shortest route.

When I lived in a house with copper plumbing the ground system ran all
over the houe.

My understanding is that a strong
electric field ionizes the air and leads
to formation of a corona. I imagine with
a sufficiently strong field, the corona
current could be in the pA range. At
least I can't imagine why not.

>
>> It occurs to me that the current due to charge redistribution could be
>> rather significant if numerous particles are striking the antenna in a

>
> Maybe aggravated by one element of the dipole being grounded
> and the other floating?

I can't comment on that, Cecil. I was
trying to keep the geometry simple with
a single vertical wire. A grounded
vertical wire in the fairweather field
will acquire a charge and charged
particles striking it should not change
the charge on it, but they will cause a
redistribution. That redistribution
doubtless produces a magnetic field as
additional charges flow to/from the earth.

It's a fascinating problem.

73,

Chuck

Here's an exercise that might add some realism. Calculate the amount
of charge a 14 awg 40 meter dipole antenna at 35 feet would have to
accumulate in order to generate a strong enough field to cause a
corona discharge. (Arcing at the feedpoint doesn't count.)

OK. So you understand that it is not
necessary that a conductor be charged in
order for a corona to be formed. It
needs only to be placed in a
sufficiently strong electric field.

But if there is no external field
assumed, then the required charge on the
wire would be that which will produce
the requisite field intensity at some
chosen place on the wire.

The "pointier" the place you choose, the
smaller the necessary net charge. Any
charge on the wire will be distributed
over a real wire but concentrated where
there are sharp points.

As the radius of curvature of a "point"
on the wire, such as a dust particle
stuck to it, approaches zero, the
quantity of charge necessary to cause a
corona becomes quite small. That's about
as close as I can come to realism, Jim. ;-)

Just call a foreign country on your cell phone. If you ask them to 'Please QSL', you might have to tell whoever it is you talk to what that means.

If they won't QSL, we can use your phone bill as proof of contact, but it's not as good as a real QSL card because how do we know that you didn't just babble into someone's answering machine for a minute or two.

The first DX award no-codes can try for and is easy and cheap to get is the CAC Award (Called all Continents) and is very similar to the WAC (Worked all Continents.) If you're really really new to radio, you might want to start with CAS first. (Called all States)

I know you're right.

They where doing great until the computers crashed then the new hams looked at us old hams, blank stares on their faces wondering what to do. They thought Field day was over at the point. Then us dino's took over and showed them what ham radio really was. Some nickle extra's even said they were going practice building their code skills again. They saw you can work stations on code that you can't work on phone or PSK31. We taught them how to solder on PL-259s and tune portable antenna & trim wire antennas.

We laughed when they lifted up the tri-bander and then had to take it down again to connect up the coax. That was funny.

I'll get back to you on that one. I've never been in a situation where I
couldn't produce RF and commmunicate. When it finally does happen, I'll
let you know if it was flags, mirrors, or smoke signals.

Of course someone could do an end run around us by just calling BuxComm
and getting the real scoop. 8^)

I don't doubt that someone might come to a different conclusion, but I
think my reasoning is pretty sound. I modeled an equal length version of
this in 4nec, and it just doesn't work very well. OTOH, turn it into an
OCF dipole, and it is a different story.

BuxComm has no need to sell an antenna as "multiband" when it isn't,
and when they have other comparably priced models that will work.

Well, sometimes dummies like me get caught up in actually thinking that
it is serious discussion. I should know better!

I would suggest that a lot of the antagonists do a little better
though. All the air goes out of an argument when they just bust on
insignificant details.

I had a fellow like that who worked for me once. He wouldn't pay much
attention to the conversation at hand. But he wanted to show he was
involved. So every once in a while he would latch on to a couple words I

was saying, and argue past me on the irrelevantly picked up point.

I guess that is okay in newsgroups. It is the sort of thing that gets you gone in the workplace.. 8^)

I make the mistake of using these groups as a learning tool, when perhaps they are really here as mental professional wrestling?

i understand that a monopole antenna is an illusion. the element is reflected by ground or a ground plane or a counterpoise and is effectively a two element set up anyway. so, somebody take me to school on this; what about a ground plane whip such as a cb antenna with another identical whip mounted upside down below it? would the bottom whip appear equal to a ground plane and allow the antenna to radiate as it was intended to? would this work in an application where a decent rf ground cannot be achieved? or where consistent antenna characteristics are needed regardless of location or environment?

George responds: Isn't it clear? Stir the world into a frenzy of anti-American responses. In effect, it is propaganda based on prevarication. In other words, psychological warfare as opposed to what the New York Times is doing, which some might call treason. The "hate America crowd" is alive and well and playing to a willing if not naive audience in Europe. I suppose we are lucky there wasn't an insulting cartoon of some Middle Eastern religious icon included with the post and attributed to the Washington Times!

Yes, but according to the references, fairweather conditions are
not a strong enough electric field to cause corona in the absence
of some other energy source.

> I can't comment on that, Cecil. I was trying to keep the geometry simple
> with a single vertical wire.

Well, a single vertical wire would have its ground plane grounded
so it might also build up a charge between the inner coax conductor
and outer conductor from wind-driven charged particles. But wouldn't
a ball on top reduce the possibility of corona just like it does
on other vertical antennas?

And make it #14 solid wire with rounded ends. I suspect the coax
connector would arc long before any corona appeared. In fact,
corona should be visible at night.

A final thought. If there were any truth to these allegations don't you
think that the Wash. Post, NY Times, LA Times, etc. would have been all
over this one!!!!.......G

Why don't you sign who you are then? I don't understand why some people
that post like to obfuscate. And I'm a regular, and I can't say I've
ever seen your call. You certainly don't make it obvious, which is your
right, but don't claim it's out there, because it's not.

How did you possibly determine what the balun input impedance was when terminated with the impedances the antenna presented on the various bands? How did you model the balun? It's almost certainly a "voltage" balun which will force common mode current onto the feedline when terminated with an asymmetrical load. Because of the common mode current, the outside of the feedline must be part of the model. Did you model the antenna with various lengths and orientations of feedlines?

I don't believe that a valid model can be made of this type of antenna without knowing and accounting for the major imperfections of the balun, the common mode current it forces, and the feedline length and orientation for the particular installation.

Jim wrote:
> i understand that a monopole antenna is an illusion.

Yes and no. An antenna can easily be constructed such that only a monopole radiates significantly. A common example is a ground plane antenna. However, the same amount of current which flows into a monopole must flow somewhere else -- to a ground plane or "counterpoise", to the Earth, down the transmission line, or to another radiating wire for example. So a monopole can't exist in isolation.

the element is
> reflected by ground or a ground plane or a counterpoise and is
> effectively a two element set up anyway.

No, an element isn't "reflected". The field from any antenna, monopole or dipole, is reflected by the ground, creating interference with the unreflected field.

so, somebody take me to
> school on this; what about a ground plane whip such as a cb antenna with
> another identical whip mounted upside down below it?

This constitutes a vertical dipole, a common antenna type.

would the bottom
> whip appear equal to a ground plane and allow the antenna to radiate as
> it was intended to?

No, it wouldn't "appear equal to a ground plane". As for the antenna radiating as it's intended to, how do you intend for it to radiate?

would this work in an application where a decent rf
> ground cannot be achieved?

Sure. A vertical dipole is a very common type of antenna. A google search should bring you a wealth of information.

or where consistent antenna characteristics
> are needed regardless of location or environment?

The location and environment can affect any type of antenna, including this one.

C'mon Mike, this is coy by half.

Look at the Subject line you've responded to.

How could you possibly have any fantasy of this being a lesson in
flower arranging?

Look at the Subject that drove this critique.

With fully 27 correspondents, only Cecil is churning out the
inconsequential (much different from insignificant) at a ratio of
146:8. With this having increased by nearly double the earlier
observed posting ratio of 9:1, how is you seem to have been
blind-sided? If you genuinely desire to discuss the serious topic of
the Google Hypothesis, I would suggest attention to this climbing
ratio. As a fact, it takes no more than a couple dozen words. A
response would hardly encompass half that.

Beyond that, and for entertainment's sake, I'll move on from the
Rodney King metaphor to Beat Takeshi Kitano's "Zatoichi" (or any of
the 25 earlier movies, or the 100 TV episodes).

Hello, and was that a shunt-fed AM broadcast tower? You might just get away with a grab at ground level. OTOH, I would think that grabbing onto a live base-insulated type tower would have serious consequences when being fed by a 10 kW transmitter. Just looking at the RF bypass hardware needed at the base to provide for tower lighting (Austin transformer or Collins lighting choke) should be enough to say "keep away" while transmitting. Sincerely, and 73s from N4GG0,

Your use of the word 'target' is interesting.

I'll follow that by quoting you,

> To begin with this is an antenna page, but we'll ignore that for now.

Then you said

> I don't like anonymous posters.

I don't like self-appointed net police but like anonymous posters I have to tolerate them. The Supreme Court has ruled that identifying oneself is not a requirement for freedom of speech, so being an anonymous poster is legal. 'Targeting' them is tantamount to stalking, which is not legal, Mr. Net Cop.

> of some other energy source.
>

That is probably based on the notion
that below a field strength of ~300
volts/meter (Paschen), voltage breakdown
in air is not possible. Fairweather
fields tend to typically be weaker than
that although 200 volts/meter is
sometimes observed.

But Paschen's number assumes parallel
plates, and not sharp electrodes, and
Llewellyn demonstrated sharp electrode
breakdown at 100 volts/meter, a strength
often found in fairweather fields.

There are many other factors that
influence electrical breakdown, such as
ionization of air by naturally occurring
radioactivity (e.g., radon, which would
be another energy source but one which
is usually present near the earth),
atmospheric pressure, etc.

So yes or no? Paschen's law says no. But
Jonassen admits that Paschen's law has
never been tested for non-parallel
electrodes of really small dimensions
and he found it doesn't hold for small
spherical electrodes at separations of a
few cm. Llewellyn reported measurements
below the predicted Paschen minimum for
sharp electrodes.

I would think so. And the coax looks
like a capacitor to DC, FWIW.

But wouldn't
> a ball on top reduce the possibility of corona just like it does
> on other vertical antennas?

It would reduce the possibility of
corona if it has a greater radius of
curvature than whatever it replaced.

So it would seem possible to have arcing at the coax
connector without having corona on the antenna.

Jim and Roy,
While this sounds like I am contradicting Roy, I believe I am simply stating things in a slightly different way. The type of mental model I express here has worked well for me over the years, in discussions with other professionals, in understanding the various antennas.

Roy says Yes and No in places here, but I would use different Yes's and No's in this case, as follows:

> Jim wrote:
> > i understand that a monopole antenna is an illusion.
> Roy:
> Yes and no. An antenna can easily be constructed such that only a
> monopole radiates significantly. A common example is a ground plane
> antenna. However, the same amount of current which flows into a monopole
> must flow somewhere else -- to a ground plane or "counterpoise", to the
> Earth, down the transmission line, or to another radiating wire for
> example. So a monopole can't exist in isolation.

While what Roy says is correct (there should rarely be any doubt) , I believe Jim's interpretation is not in-valid and can be a very good "mental model" of antennas.. The monopole needs something to be its "other half" as Jim says. In a ground plane antenna, the "plane" is the other half. In a dipole (vertical or otherwise) the bottom half is the "other half". Any and every circuit needs two connections to have a complete circuit. Sometimes, with antennas, the "other half" is not obvious to everyone, but it will always be there and Roy's words; "...the same amount of current which flows into a monopole must flow somewhere else .." addresses this "other half" issue. I believe Jims words are sufficently close to Roy's words to be equivalent. So, I would say, Yes. There ain't no such thing as a monopole, you just don't realize what is acting as the other half (If you think you have one).
I believe this basic concept can be applied to almost every antenna configuration to help understand, to a great extent, what is "going on"

Jim:
> the element is
> > reflected by ground or a ground plane or a counterpoise and is
> > effectively a two element set up anyway.
> Roy:
> No, an element isn't "reflected". The field from any antenna, monopole
> or dipole, is reflected by the ground, creating interference with the
> unreflected field.

Actyually I'd say Yes. I believe the following words describe precisely the same thing Roy said.

In electromagnetic field theory studies, there is something called the "Method of Mirrors". This is a way to calculate a field when there is a conducting plane nearby. To model the conducting plane is mathematically very complex. You actually can model the conducting plane as a mirror which has produced a "reflection" of the element in it. This reflection, because of the properties of the field, has the opposite sign (polarity) and is mathematically handled as though it was another element in the place conducting plane. . It turns out that with this new model, it is much easier to do the math to get the total field. (NO I can't do it any more...don't actually think I was doing it the first time! bad instructor). So, I would say that it is a pretty good analogy to say that the ground plane "has the effect of" reflecting the monopole and therefore providing the "other half".

>
> so, somebody take me to
> > school on this; what about a ground plane whip such as a cb antenna with
> > another identical whip mounted upside down below it?
>
> This constitutes a vertical dipole, a common antenna type.

You have, ideed described a dipole turned vertical...and I feel you have identified a very important concept in antennas. Just about every antenna can be understood better if you start out by finding the "dipole" hidden within. beams, G5RVs end-fire arrays, broasdide arras, J-Antennas, colinears...

> would the bottom
> > whip appear equal to a ground plane and allow the antenna to radiate as
> > it was intended to?
>
> No, it wouldn't "appear equal to a ground plane". As for the antenna
> radiating as it's intended to, how do you intend for it to radiate?

Per my above, I'd say that Jim's description is a relatively good model to have in your head. If the groundplane "acts" similar to a mirror giving rise to the equivalent of the "other half" of the dipole, and that result is equivalent to another "half" mounted below it, I feel this only leaves us to debate the real meaning of Jim's words "...appear equal to ...". I think that is a pretty good way to think about it.

> would this work in an application where a decent rf
> > ground cannot be achieved?
>
> Sure. A vertical dipole is a very common type of antenna. A google
> search should bring you a wealth of information.

Ditto on what Roy said, plus: The antenna commonly called a "J-Pole" is "the same thing" as a half wave dipole, but stood on end, vertically...EXCEPT it is fed power at its bottom end not in the middle.

As an asside...I'll also add that this concept of a "decent RF ground" is something that many seem to believe is some sort of an absolute thing. Comments labout wanting to get a wire to a ground rod as being the solution to all things...the hunt for the "good RF ground". I have a tongue-in-cheek twist on an old saying: "A ground's a ground, the world around." An RF ground is somwhat of a myth, even on a solid sheet of copper, but some think there is this absolute GROUND that all things must be connected to in order for things to work correctly, or solve problems. Of course I know that, as Jim states, that the bottom half of this vertical dipole is the "other half" of the antenna and might be considered a "ground" but is is nothing more than the other half of the antenna and hads, and needs, absolutely no relation a zerp potential reference, whatever that is.

> or where consistent antenna characteristics
> > are needed regardless of location or environment?
>
> The location and environment can affect any type of antenna, including
> this one.

Here, Jim is getting into wording that may mean different things to differet people, but what Roy says is fact. Antennas carry RF and things like capacitance to nearby objects and currents induced into nearby conductors; always, always can have an effect on an antenna regardless of it's particulat construction. There will be different effects for different types of antennas, but this is all dependent on the antenna and the place it is hung. There may be some forms of antenna that are less susceptable to nearby objects in certain places relative to the antenna, but this is all random--that is to say; it depends on the antenna and your back yard.

> plane "has the effect of" reflecting the monopole and therefore providing
> the "other half".

The reasons I objected to the concept are twofold. First, there's some ambiguity in what constitutes the "ground plane" which does the "reflecting". The "ground plane" of a ground plane antenna reflects nothing except very high angle radiation. So it doesn't act as a mirror in any sense. Secondly, the Earth does reflect the field, but the result isn't anything like a mirror. Only a perfect ground ends up creating the same shaped field from a grounded vertical as a free space dipole. Real ground creates a field shape which is very significantly different. So the model of a mirror-like ground isn't at all a good one; its use leads to incorrect conclusions so I don't feel it should be used unless the user clearly understands that the conditions under which it's valid aren't ones you can achieve very well at all -- except with salt water or with a very large (several wavelength radius) conducting plane perhaps at UHF.

Well, no, a typical "ground plane" doesn't act like a mirror, as I explained above. And even the Earth does a very poor job of acting like one. At best, it's a dirty mirror which isn't uniformly dirty. The only common exception is salt water, which does a fair job.

Yes, "ground" is a concept which is almost universally misunderstood and misused. Calling something "ground" seemingly imparts magical properties to it. Very often, it gets in the way of understanding how antennas work, and people would be better off forgetting about it. It's not uncommon for an EZNEC user to ask how to model a "ground" or to specify that something is a "ground", meaning some sort of elevated "counterpoise" or "ground plane". I explain that the program doesn't know or care what the user might consider to be "ground" -- all it knows and cares about are conductors and currents. People hoping to understand antennas would be well served by doing the same.

That's generally when you find out your rig might need repair, when
someone reports your audio is distorted or garbled.

IC-725 Rotary concentric knob (outer=power inner=mic) on front panel 10W
(ccw) to 100w (cw)

manual: http://www.icom.co.jp/manual/external/transceivers/IC-725.pdf

or did you mean IC-725A? totally different beasty ;)

IC-725A Small rotary control on front panel 5W(ccw) to 100W (cw)

manual: http://www.icom.co.jp/manual/external/transceivers/IC-725A.pdf

(values given for FM/SSB/cw)

Adjustments are covered in the relevent manual.
If 5W or 10W is too much for the power supply consider a bigger supply (20A
+)

You are correct, I couldn't. But what I got was enough to tell me that with the two sides of equal length, there wasn't much need to go any further. Cannot some antenna characteristics be modeled without the entire system in place? I'm no expert, so I'll ask the question: Is there some Balun that will make a 135 foot equal length antenna perform on 80-10 meters?

How did you model the balun? It's almost certainly a "voltage"
> balun which will force common mode current onto the feedline when
> terminated with an asymmetrical load. Because of the common mode

> the common mode current it forces, and the feedline length and
> orientation for the particular installation.

It isn't whether my model is exceptionally valid. I don't know what the balun is that they use, so that sense it doesn't matter anyhow. You would know much better the balun that would make this antenna work.

I'm just looking at what is there, and by looking at both the context of the advertisement, references given for their other antennas and the like, I'm just saying that I suspect that that antenna is a OCF dipole.

Their G5RV antennas do *not* have an L1 and L2 to designate length of the sides. If that antenna has an equal length side, it is the only one on the site that does. Yeah, I know they are not really G5RV's.

In addition, is BuxCom going to try to sell a product that apparently doesn't work? I don't see any of the hype that tends to go along with

the "magic" antennas we sometimes hear about

All of the above just about convince me that the antenna in question is an OCF dipole, and that the description and image is a big typo.

Others may take it at all at face value, disregard all the evidence to the contrary, and assume that the sellers are just trying to hoodwink a gullible public into buying a non-working product.

That doesn't make sense to me. YMMV

> entire system in place?

Yes, but you have to at least include the whole antenna -- you can't tell much about a two-element array by modeling a single isolated element. In the case of an OCF dipole, unless heroic efforts are made to keep common mode current off the feedline (which the balun doesn't achieve), the feedline is part of the antenna so, like the second element of an array, it can have a major impact on the both the pattern and impedance and has to be included in the model. The balun, feedline length, and feedline orientation all play a role in determining how much current goes down the feedline part of the antenna and where that part is. So you have to know at least that much to get a meaningful result.

I'm no expert, so I'll ask the question: Is
> there some Balun that will make a 135 foot equal length antenna perform
> on 80-10 meters?

"Perform" is one of those binary terms that depend on where you put the dividing line. But the answer is that the only practical way you can achieve a reasonable impedance match to a coax feedline on all bands with a center fed 135 foot antenna is to introduce a fair amount of loss. This could be in the form of a resistor at the feedpoint, for example. Then you'll have an inefficient antenna at least on some bands. Alternatively, you can have low loss at the feedpoint but a lousy impedance match. Then you'd have a lot of loss in the feedline if you fed it with coax. The bottom line is that you'll have poor efficiency on at least some bands if you feed it with coax, no matter what you do --

short of putting either an adjustable or very elaborate fixed matching network at the feedpoint.

Nearly any ham can measure the SWR but almost none can measure the efficiency. So many antenna manufacturers have produced lossy antennas which exhibit a low SWR. This is perfectly acceptable to many amateurs, as evidenced by glowing reviews for a number of antennas which can be shown to be quite inefficient such as the B&W T2FD or the Isotron. Those amateurs would positively say that such antennas "perform", and this can't be disputed since the judgment is entirely up to them.

> . . .

> Others may take it at all at face value, disregard all the evidence
> to the contrary, and assume that the sellers are just trying to hoodwink
> a gullible public into buying a non-working product.
>
> That doesn't make sense to me. YMMV

"Working" is like "perform" -- the threshold is different for different people. But a quick scan of reviews for the Buckmaster and Alpha-Delta OCF antennas (the latter apparently manufactured by Buckmaster) show high satisfaction from at least the users who have taken the time to post reviews. Whether you or I would be happy with one depends on our personal criteria.

Let's be honest, the only thing you can repair is some old piece of junk tube rig because the technology is so simple. You could never repair a modern rig, because like most dinos, you have ever evolved into the new technology because out of fear, you cling to what is old and comfortable.

Wow, you guys must have been part of the most ignorant group of individuals ever put on this earth using the most crappy computers and equipment. All the computers crashed? Wow, how could that have happened?

I am surprised that the newbies are still using ham radio after hanging around with you dinos. Computers broke down and you could not help fix them. That's right, the computers don't run on tubes and that is the extent of your knowledge as dinos.

Now anyone that uses PSK knows that you can work a station that you cannot hear with the human ear. Anyone that knows CW knows that you have to hear CW in order to copy it. So as a dino, you are showing your ignorance of technology and probably have never heard, seen or used PSK or you would never have made that statement.

My Field Day group had a good laugh when I pointed out your message to them. They said you obviously don't know what you are talking about - at least concerning anything modern.

So you old, used up, worthless dinos laughed at the newbies, belittled them, and you could not fix or use anything modern. And you think those newbies are going to stick with ham radio? Probably not. Old thinking buggy whip hams like yourself need to stay locked in your shacks talking only with other dinos about your illnesses and the like, and stay away from the younger technology savy crowd as they might be really interested in ham radio and your old crap is going to scare them away.

They don't want to learn about buggy whips when they are interested in driving a modern car - get it old timer?

At:

http://www.commparts.com/catalog/index.php?cPath=9&sort=2a&page=2

The OCF's are labeled as Windoms and drawn with unequal elements.
The ones drawn with equal elements are not labeled as Windoms.
I would infer that they are different but I could be wrong. I sure
would like to know what's inside the "balun".

Thanks for your comments Roy. I dispute nothing you said (like I'd even try). The area I focus on is that a beginner (and this was clearly such a guestion), trying to understand antennas shouldn't be given too many of the more esoteric aspects you point out such as a real earth ground-plane and radials on a real antenna.
I figured that a simple analogy, as long as it either holds up in the future, or its short comings can be easily understood later, is a valid starting point in a complex subject such as this. Ground losses and radiation angle effects of the real ground plane asside, the chosen counterpoise whatever its form, does indeed provide the "rest of the story" (:-) just as the OP has pretty much igured out and was looking for validation.

I believe the "trick" is a getting well-working analogy...something that will not be contradicted by the deeper understanding. (use the garden hose analogy to explain current, but know when to point out its shortcommings).

A 1/4 to ~1/2-wave vertical monopole used with the typical radial ground system of MW broadcast stations actually does _generate_ very nearly the same pattern and peak field as a free-space dipole of twice the length as that monopole. This has been demonstrated by field measurements going back to 1937 (George Brown, et al).

It is only after the radiated wave leaves the vicinity of the antenna that the conductivity of real earth begins to affect it. These effects accumulate, and at distant ranges, there is more reduction in the groundwave field than at angles above the horizontal plane

That is why the pattern takes on the shape shown for it by pattern analysis of this hardware for an infinite distance -- which has zero field in the horizontal plane. But it doesn't have that shape as it leaves the radiation system.

As a *very* loose definition of work, I would say that I would expect
an antenna that advertises itself as an "all band" would allow a modern
Transceiver to put our something like full power, that is, to not fold
back on power. Oh yeah, and to radiate something. I don't see a tuner in
that diagram, so take your pick whether they are assuming an internal tuner.

Certainly there are a lot more stringent criteria. But that would seem
to suffice for many hams. 8^)

if i bought a similar antenna, i'd assume i'd need a tuner. i mean i needed
one with my 120 foot (60 + 60) foot doublet. you don't even need a real
fancy tuner, mine was a small Yaesu digital. it did have some problems on
40 meters (high Z?).

Indeed it does. Many are happy with an antenna that gives a low SWR on all bands and radiates 1/100 of the applied power. You can work the world with one watt of radiated power. On the other hand, give a ham an efficient but poorly matched antenna that causes his rig to fold back and produce only 10 watts, and he'll be an unhappy camper. So the first antenna "works" but the second doesn't, even though the signal it radiates is 10 dB stronger.

I know you're right.

These new modernized hams want everything to be easy just like flipping
the on-off switch on an appliance. We try and tell them that ham radio is
more than just operating an appliance, but they won't listen. Then when
murphy's law kicks in they don't know how to deal with it. I feel sorry
for them, but it's really not their fault that licensing has been dumbed
down over the years. The phonies did notice after we put the broken
computers in the dumpster that the bands sounded much better without all

the computer generated noise on their receivers. And their contacts per minute increased. They realize now that when equipment fails it's nice to have skills you can fall back on that will let you keep communicating. Especially important during emergencies. Hams wouldn't look good if during an emergency we couldn't communicate.

And how many times has that happened to you? I'll bet never. You're too
smart to smoke your finals. Normally when I hear someone lost their
finals it was a result of operator error, or an act of stupidity.

Well said but now everyone knows the secret.
